DR. ALFRED H. CARTER, F.R.C.P., has been elected to the chair of Therapeutics in Queen's College, Birmingham.

WELLINGTON COLLEGE SORE-THROAT.

BY J. G. BARFORD.

(*Continued from page 275.*)

TWO distinct forms of sore-throat occur among the residents at Wellington College. The one is a simple, non-infectious malady, such as may be seen elsewhere, and is apparently dependent on sudden changes of the weather or any other cause giving rise to a chill; the other is an infectious malady, analogous to, if not identical with, a form of sore-throat very prevalent in the past in ill-ventilated and overcrowded hospitals, now happily of rare occurrence, and best known as "hospital sore-throat." During the time I was dresser and house surgeon at St. Bartholomew's Hospital, now more than thirty years ago, I noticed that "hospital sore-throat" was a common precursor of erysipelas among the patients in the surgical wards. Subsequent experience in private practice, and the comparison of that experience with the special opportunities afforded by attendance for twenty-four years on the boys at Wellington College, led me to the conclusion that from some cause or other the throat affections at Wellington College often differed very materially from those I saw among my private patients elsewhere. As an example of what occurred at Wellington College I may relate the following interesting cases. In the year 1861 two boys were taken ill, with feverishness and sore-throat. This was in the second year of the existence of the College. They developed an ambiguous rash, now recognised as no uncommon accompaniment of both diphtheria and septicæmia. They were seen by four medical men, one of whom thought the affection might be suppressed scarlatina, another leaned to the view that it was more in the nature of diphtheria, but all agreed that it was very ambiguous and grave. I had seen nothing of the kind either at the Children's Hospital in Great Ormond-street, or at St. Bartholomew's Hospital, or at the Hôtel Dieu in Paris. These cases made me feel grossly ignorant of my profession, but I had some comfort in seeing that other men of large experience and high repute seemed to know no more about it than I did. The cases did well in the end, and we comforted ourselves with the feeling that "all's well that ends well." Seen by the light of subsequent illness at the College, I have no doubt that they were cases of pure septicæmia arising from some infective process in the locality, and connected in one way or another with the decomposing organic matter with which this district abounds. It could scarcely at that time have been sewage contamination, for the College had only recently been opened, and the district was previously uninhabited, being, as the article in *The Times* described it, "a bleak inhospitable moor." These were not isolated cases of curiosity. One morning I was breakfasting with the head master, the present Archbishop of Canterbury, as I commonly did in those days in order to talk over school affairs, for I was at that time very much in the head master's confidence, as indeed were all his subordinates; for just as in proportion we had confidence in him (and this was unbounded), so he trusted us. There was a common aim among us to make Wellington College the best and the healthiest public school in the world. Two hours after breakfast I received an urgent message to go and see Mrs. Benson. I found her with a patch of diphtheria on her throat and very indisposed. At the breakfast table she had appeared to me perfectly well, chatty and charming as usual. The district at that time was free from diphtheria. Then the question arose, Whence the source of this attack? Such cases reopen to some the two rival theories of "spontaneous generation and development from pre-existing germs." But other cases arose quite as remarkable, and as it will be interesting to link experience in the past head master's house with that in the present head master's house, this will settle the point that both past and present head masters knew of the occurrence of diphtheria at Wellington College, for both had had it in their own families; the one in quite the early days of the College, the other in the middle period of its existence. These facts, taken into consideration with the subsequent and recent outbreaks, may give some clue to the cause, at present in obscurity. I was asked by Mr. Wickham to go and see some members of his household. I found Mrs. Wickham, the housekeeper, and one of the maids with a diphtheritic sore-throats; the other members of the family were free from it. The architect and sanitary adviser of the College was sent for; he could find nothing wrong with the sanitation of the house. I could trace no introduction of the disease from without. I persisted that there was something wrong within the house, for two out of the three had not been outside within the usual period of incubation. I got each patient to relate to me everything they had done during the past week. I found that Mrs. Wickham and the maid were in the habit of going to the housekeeper's room, and this was the only place where the three affected persons could be said to have been exposed to a common cause. Mrs. Wickham sat in a chair in a corner of the room to receive pence, I think, from poor children for a little bank she kept going for them twice a week. The housekeeper sat there at other times; the maid was in the habit of going to the same corner. I advised Mr. Wickham to have that spot searched both within and without the walls. Here the mischief was found. A stack-pipe drain had become blocked, and the soil saturated with damp. Here, again, the question arises, Where had the germs been, and how did they get there?

It should not be supposed that the development of these throat affections and their complications, going on in one case to diphtheria and in another to erysipelas or pneumonia, or exhibiting true toxic symptoms, are confined to Wellington College delta, to the exclusion of other low-lying portions

Digitized by Google

of the neighbourhood. The low-lying districts of Camberley, of Frimley, and Blackwater, where the Staff and Royal Military Colleges are, have gained an unenviable notoriety by the repeated outbreaks of diphtheria, outbreaks so fatal as to call for public investigations. At the last annual inspection of the cadets by the Duke of Cambridge, his Royal Highness congratulated them on their appearance of healthiness and vigour, yet within a stone's throw of where his Royal Highness spoke there was diphtheria. Here, then, in the midst of general good health, diphtheria crops up as if of spontaneous origin, or from the sudden bursting into vigour of some phase of dormant germ life. But why thus so long dormant and then suddenly active? Bacteriologists fail to explain. Nor are these occurrences confined to the more populous districts, as the following cases will illustrate. A mother and her daughter spent a September afternoon picnicking in one of these marshy valleys. Next day both were indisposed, and the following evening had well-marked symptoms of severe diphtheria, which proved fatal in both cases in a few days. The amount of deposit of diphtheritic membrane on the throat was *not* in proportion to the severity of the constitutional symptoms, and death took place from toxæmia. The house they occupied was an isolated one free from insanitation, placed on the brow of a hill, and raised some hundred feet above the marsh valley. They did not doubt themselves, nor do I doubt, that they caught the disease on the afternoon they spent picnicking in the marsh. But diphtheria is not the only disease these marsh lands are capable of generating.

Septicæmia, like diphtheria, has also prevailed at Wellington College, and not there alone in the district, as the following cases will illustrate. A few weeks anterior to the two cases of diphtheria above related, a young lady home from school spent an afternoon playing in the valley visited by these diphtheritic patients. The following day she was generally indisposed, and when I saw her I found her with some slight tenderness of the knee-joints; a tender line could be found running up on the inside of each thigh, and there was some tenderness and distension of the abdomen. My experience among the boys of Wellington College, where I had seen septicæmia over and over again, had taught me the grave significance of these symptoms when associated with such a history. Within forty-eight hours all the graver indications of septic infection displayed themselves, giving rise to peritonitis, pneumonia, pleurisy, pericarditis, endocarditis, and, lastly, cerebral effusion. The child hovered for a fortnight between life and death, for as the inflammatory action in one organ yielded a little to treatment it lit up in another. The parents, who are more than ordinarily intelligent people, lost all hope under the exhibition of such desperate symptoms, but I had seen boys recover at Wellington College, and I was hopeful that this girl might, which she ultimately did.

As my personal experience, extending over a period of thirty years in private practice, had taught me that these grave cases of septicæmia were mainly confined to the low-lying marsh valleys of the Blackwater river, which divides Berkshire from Hampshire, or the marsh valleys adjacent to it, one of which forms the delta of Wellington College, I have during that period been able to come to no other conclusion than that the abundance of putrescent organic matter with which these valleys abound plays an important part in the production of both diphtheria and septicæmia. Just as these sand and marsh districts are prolific in most forms of fungus life in autumn, it is not unreasonable to infer that they would be equally favourable to the germination of pathogenic micro-organisms which bacteriologists believe are closely allied to fungi in their origin, nature, and method of propagation. As far as my observation goes, sewage contamination of soil has little or nothing to do with their production. Certainly diphtheria and septicæmia do occur where no indication whatever exists of the influence of sewage contamination, as the following case will illustrate. A young man was riding his bicycle through the valley of the Blackwater in the evening, when he met with an accident, he supposed, and was thrown, and lay by the roadside for some hours without assistance. There was no residence near, and he, as far as could be told, had had either concussion, or had fainted. I think the latter. There were no external marks of injury, but the following day he had pain in his joints, followed by sickness and the significant tenderness of the knee-joints and the tenderness up the inside of the thighs mentioned in the preceding case of septicæmia. His mind was perfectly clear, and remained so, but peritonitis, pneumonia, pleurisy, and such cerebral effusion as to produce total blindness, so that he could not even distinguish a candle when brought near to him, yet with perfect clearness of intellect, left no doubt that the cerebral serous membrane, like that of the joints and the pleura and the peritoneum, had become affected. Such is the nature of septicæmia that serous membranes are the most susceptible to its influence. Nor is this the only case in which I have seen total blindness produced. In one of the fatal cases of septicæmia at Wellington College the poor boy lost for a time all power of vision, yet his mind remained clear. During the progress of his illness vision returned, and disappeared again, and returned again, and at last he died of pyæmia, to which all cases of septicæmia tend if the patient lives long enough for the more acute inflammatory symptoms to subside and pus to be formed.

All the cases of septicæmia or blood poisoning I have seen begin with the apparently simple sore-throat so well known among the boys at Wellington College, just as the diphtheria does. The throat "opens the door" for the introduction of the poison, for if the sore-throat is adequately dealt with when it first arises, the graver diseases are not elaborated or developed. It is for the bacteriologist to decide by experimental investigation whether the poison in both diphtheria and septicæmia as they occur at Wellington College and the adjacent districts consists of varieties of the same species of micro-organism cultivated from non-pathogenic forms into pathogenic phases of existence by the quality of the soil in which they fructify, or whether they are at all times disease-producing species only waiting their opportunity to permeate the system and to accomplish their deadly work. Viewed from the clinical standpoint, my inclination is to regard both the diphtheria and septicæmia, as seen at Wellington College and thereabouts, to be phases of disease having a common cause, and that cause to be in the nature of the soil of the locality, which all the sanitation there adopted has been so far powerless to eradicate. The soil must be "sterilised," and until it is, diphtheria and septicæmia will recur at Wellington College, and bring the school into more unenviable notoriety than it now possesses.

METEOROLOGY ON BEN NEVIS.

THE establishment of an observatory on Ben Nevis was one of the most substantial advances ever made in this country in the study of *meteorology*. The observations there recorded have already proved of immense service in promoting our knowledge of the new-born, but already vigorous, science of weather, and no doubt we may look to the same source for much valuable information in the future. The situation of Ben Nevis is not all that could be desired for a national meteorological observatory, among its defects being its liability to fog, but it possesses some considerable advantages, such as elevation and command of the westerly air currents from the Atlantic. To those who have given the subject little attention some of the recorded facts will seem surprising. Thus, we learn that during four days in January, 1891, Ben Nevis, along with the north-west of Scotland, "was enveloped in a warm damp current of air, with the thermometer standing from 25° to 30° higher than over the south of England." This will, however, not seem strange to those who have practically studied the meteorology of these islands and who understand how much more temperature with us depends upon longitude than upon latitude, our climate being much less influenced by our geographical position than by the warm air and fluid currents from the Atlantic. Thus, to take two extremes, Monach in the Hebrides and Penzance in Cornwall possess two of the mildest and most equable winter climates in Great Britain.

One of the most curious of meteorological phenomena has lately been studied with great care on Ben Nevis. We allude to the phenomenon known as "silver thaw," a paper upon which by Mr. R. C. Mossman appears in the recent issue of the Journal of the Scottish Meteorological Society. By silver thaw is meant rain falling when the air is below freezing point and congealing as it falls. The phenomenon "points to an inversion of temperature at the time,

Digitized by Google

the temperature on the hill-top being considerably lower than at higher altitudes." During the six years 1885-90 inclusive, 198 cases of silver thaw were observed, lasting in the aggregate 873 hours, or a mean duration of four hours and a half for each case. In December, January, and February the average duration of each case was six hours, whereas during the other months of the year it did not continue more than three hours. The phenomenon was found to be practically confined to the winter months, being rare from April to October, and no case having been hitherto recorded in the month of July.

Careful observations have been made with the view of determining the conditions of pressure prevailing at the time of the occurrence of silver thaw. It has been found that "for the 198 days on which the cases were observed on 137 the distribution of pressure was cyclonic, and on sixty-one anti-cyclonic. Almost without exception it was found that "in the anti-cyclonic conditions there was a cyclone central off the north-west coast of Norway, while the centre of the anti-cyclone was over the south of England and Ireland; while in the cyclonic cases Ben Nevis was within the area of low pressure, the centre of which was off the north-west coast of Norway, while the anti-cyclone was over the Iberian peninsula." The lowest temperature at which silver thaw occurred was 18°, and it was of rare occurrence below 27°. Fully 90 per cent. of the cases occurred between 28° and 31·9°. Hence the greater number of cases occurred just before a thaw.

Some interesting facts have been collected regarding the condition of the wind at the time of silver thaw. "The mean velocity of the wind under cyclonic conditions was twenty-one miles per hour; under non-cyclonic seventeen miles per hour. As these were comparatively light winds for that exposed situation, gradients in the vicinity of Ben Nevis were slight. It rarely occurred that the wind attained the strength of a gale during silver thaw. Fully 90 per cent. of the cases were observed when the wind was below Force 4 on the Ben Nevis scale, 0—12 corresponding to a velocity of thirty miles per hour. On the other hand, calms were rare during the phenomenon."

As regards the thermometric and barometric variations about the time of silver thaw, "in cyclonic cases of silver thaw temperature began to rise fifteen hours before the phenomenon commenced, and continued rising during the occurrence, then fell until the sixth hour after it had ceased, when it rose again. The barometer was falling steadily till the phenomenon set in, rose during the thaw, and until nine hours after it had ceased, when it began to fall again, this fall coinciding with a distinct backing of the wind and rise of temperature. In anti-cyclonic cases temperature was rising for eighteen hours before, and continued rising till three hours after the phenomenon, and then fell steadily. The barometer was rising till the fall of silver thaw commenced, and thereafter continued falling steadily during and after the phenomenon."

As regards the distribution of cloud on these occasions, it was found that "the most common type of cloud which preceded both cyclonic and anti-cyclonic cases of silver thaw was cirro-cumulus, frequently accompanied by cirrus and cirro-stratus. These began to form many hours before cumulo-stratus, the prevailing low-level clouds observed during the phenomenon; thus showing that the higher strata of the atmosphere came first under the influence of the moist current, which took from three to eight hours to descend to the height at which cumulo-stratus forms. Shortly after this cloud appeared it descended and enveloped the summit in mist. During the occurrence of silver thaw, and indeed for some time before and after it, the hill-top was wrapped in cloud."

It has been found that the occurrence of silver thaw has some relation to the prevalence of storms. Thus "73 per cent. of the cyclonic, and 63 per cent. of the anti-cyclonic, cases of silver thaw were followed or preceded by gales at some of the twenty-seven selected stations on the northern and north-western coasts of Scotland." This fact is to be noted in connexion with the other fact already adverted to, that high winds were rare at the observatory itself on the occasion of silver thaw. The occurrence of silver thaw preceded the setting in of gales in about 75 per cent. of cases, the further north lighthouses showing the greatest number of storms. The depressions which brought about the phenomenon of silver thaw on Ben Nevis almost invariably travelled in a north-east direction.

The general result of the observations taken renders it probable that "the part of the atmosphere in which silver thaw occurs is of considerable horizontal, but small vertical, extent." Such observations as those recorded by Mr. Mossman are very interesting, as showing the advance of meteorology as a science. They are also very encouraging to climatologists, as proving the rapid accumulation of trustworthy data, available for working out the very abstruse, but most interesting and important, problems relating to the influence of climate upon health, racial vigour, and longevity.

POOR RELIEF.

THE very difficult question of providing relief for the necessities of the poor which shall not involve the somewhat vague reproach of pauperism has elicited among other attempts at its solution a brace of Bills, endorsed by Mr. Bartley, for dealing in the one case with relief during the working period of life, and in the other with the support of old age. The principle of these two Bills is that relief is to be accorded in proportion to the measure of self-help for which the recipient can claim credit. Thus the "Out-door Provident Relief Bill," as it is entitled, is intended to deal with the cases of such paupers as are rendered destitute by temporary or permanent illness or by widowhood, and it proposes to empower the guardians of the poor to grant out-door relief to such applicants to an extent proportioned to that in which they have out of their own savings maintained themselves during the period of distress. Thus a poor man destitute through illness, and still ill when the sick benefit of his friendly society or club is exhausted, may receive from the guardians out-door relief of the same amount, and extending over the same period of time, as that which he has already received as the fruit of his own providence. Similarly, in a case of chronic illness, he may receive permanent out-door relief if he has maintained himself during the illness for a prescribed period of time, varying with the applicant's age, of from six to eighteen months. The case of a widow is dealt with in an analogous way. Again, in the case of the Pensions Bill the benefit is to be extended to three classes of recipients—(1) persons who have never previously received poor relief; (2) those who have made some provision, though partial, for themselves; and (3) those whom exceptional illness or losses commend to the special consideration of the local authorities charged with payment of the pensions. In all cases a conviction of crime or drunkenness, if within the terms of fifteen and ten years respectively, is to operate as a disqualification. Such in brief is the scheme put forward in these Bills, and it may at once be admitted that, as compared with some other schemes that have attained to greater publicity, it has the advantages of superior moderation and economy. In adopting it we should not be so utterly at sea as to its probable consequences as in adopting, for example, Mr. Chamberlain's or Mr. Chas. Booth's projects. The author of the present scheme is even sanguine enough to speculate that its adoption would result in a diminution of the Poor-rate, but here he will hardly convince his audience. The principal cause of pauperism is not sickness and not extravagance, but irregularity of employment; and while this grievous disadvantage besets the condition of the labouring classes, pauperism must and will continue in our midst. The most meritorious scheme for rescuing the poor from the Poor-law which omits to take account of this fact will necessarily fail, and this is the main reason why we cannot look hopefully upon Mr. Bartley's scheme. But it has other and practical faults of very serious import. By making crime, drunkenness, and pauperism disqualifications for the benefits to be conferred, it casts upon the authorities who must administer the Act if passed a burden of investigation which must prove unmanageably great. By what process of inquisition are they to discover whether an applicant who puts forward a claim has incurred during a period of ten or fifteen years any of the disqualifications enumerated? The comparatively simple inquiry as to a pauper's settlement proved under the old law so onerous and expensive that the Legislature was constrained to cut down the scope of the inquiry and confer a settlement upon a three years' residence. How the much more elaborate inquiries involved in the present project are to be carried out does not at all appear, and we

Digitized by Google

much suspect that the author of the scheme has obtained his peace of mind upon this point by the simple expedient of shutting his eyes to the difficulty. But the defect is one that would be fatal even to a larger and more promising project, and we must confess that we do not find in the two Bills now under notice much help towards the solution of the problem to which they are directed.

LUNATIC ASYLUM REPORTS FOR 1891.

Barnwood House Hospital for the Insane, near Gloucester.—The medical superintendent reports that there were 67 male and 87 female residents in the institution on Dec. 31st last. The recoveries during the year were at the rate of 43·4 per cent. of all the admissions. This rate for the last fifteen years averaged 46·8 per cent., and for the last five years 57·2 per cent. We quite agree with Dr. Needham in the remark that these percentages of recoveries warrant him in making. "When it is remembered," he says, "that patients are received here practically without selection, and in the order of their application, and having in view the obviously incurable character of many of the cases on admission, there would seem to be no justification for the statement that this and other hospitals and asylums for the insane are not as successfully combating disease as other institutions which have as their object the cure of diseases which are more entirely physical in their nature." The four deaths during the year were all from ordinary causes, and gave a proportion of 2·5 per cent. to the average number of patients resident. A considerable proportion of the inmates and of the staff were attacked by the influenza. The outbreak was characterised by a great tendency to relapse, and a curious occasional increase of temperature for some time after apparent convalescence had been reached. In the general management of the asylum the continuous effort has been made to preserve its domestic character, and conduct it less like an institution than a large private house of good type, to make it as little an asylum and as much as possible a hospital and a home. The working party of gentlemen has continued its operations, and a new and fascinating occupation has been found for the ladies in ornamental basket work, which has become very popular. The governors record their great appreciation of Dr. Needham's services. These services will, we are sure, be as successfully devoted by Dr. Needham to his new office and work as a Commissioner in Lunacy. No one grudges him his well-merited and well-earned promotion, while his accession to the board will bring to its councils all the weight of a matured and practical experience in lunacy work.

Glamorgan County Asylum.—The superintendent reports that on Dec 31st, 1891, the numbers were 472 males, 468 females, total 940, showing an increase of 15 males and 13 females. The male admissions were more numerous than in any previous year since the opening of the asylum, and the limited accommodation points to the necessity for new buildings. Dr. Pringle says: "In this, as in former years, I have had to deplore the admission of epileptics, who had been so from childhood, and yet had married and become parents. One woman lately told me she got married because 'everybody' told her if she did so the fits would leave her. I have seldom an opportunity of testing the mental capacity of the partners of such people, as I generally find on inquiry that they have gone to America, or some other distant place as far away as possible from their unhappy mates, and have left their miserable offspring to be maintained by others; and I do not wonder much, since to be tied for life to one of these unhappy creatures is more than can be expected from any average mortal. The deplorable ignorance and recklessness displayed by such marriages, and the grave consequences to the children born of them and the ratepayers, to whom many of them become permanent burdens, make me often think that the schoolmaster is abroad to little purpose, and that it ought to be made a criminal offence to enter into such marriages, or for anyone to celebrate or register them." The discharges of the year give a percentage of recoveries on admissions of 28·8 for males and 30·1 for females. Of the 73 cases recovered 15 were discharged under three months' residence, 20 under six months, 17 under twelve, and 10 from one year to two years; after periods varying from two to five years 9 got well, and from five to ten years 2 got well. The deaths numbered 110, or about 11 per cent. on the average number resident. Eleven of the deaths were from influenza and its sequelæ. Dr. Pringle tells us that "the malady occurred at both our asylums, but was most severe at Parc Gwyllt, which stands about 300 feet higher than Angelton, and has its wards heated at a uniform temperature of sixty-two degrees, whereas at Angelton the wards are chiefly heated by open fires, and in very cold weather cannot possibly be warmed so well or uniformly. Warmth, therefore, seemed to increase the virulence and fatality of the disease." We are scarcely prepared to accept this as the true solution of the difference, as it is so contrary to general experience in dealing with this malady. Additional laundry machinery has enabled the patients to have two changes of underlinen weekly, and the efficiency of the kitchen department of the Angelton asylum has been greatly increased by the substitution of a new cooking apparatus for the old worn-out one. The commissioners in their report intimate their strong desire for some more special supervision and training for the idiot children. "We must urge (as we have so often done in other asylums) the committee to consider whether they cannot join with other counties in setting aside a block, as is done at the Northampton asylum, especially for the idiot children, with special attendants able not only to look after but to instruct and train them. The initial expense is of course greater than their present cost, but no child here is in existing circumstances ever likely to do anything but end his days in the asylum, and be for ever a charge upon the ratepayers, whilst with a little training not a few may be able hereafter to earn their own living; and so upon economical as well as humanitarian grounds we urge this step upon the committee."

THE ROYAL BRITISH NURSES' ASSOCIATION.

THE Right Hon. David Evans, the Lord Mayor, accompanied by the Lady Mayoress, presided over a meeting held in support of this Association at the Mansion House on Friday last. The President, Princess Christian, who has taken a deep interest in this scheme for ameliorating the condition of nurses generally, was announced to be present, but owing to recent family bereavements was prevented from attending.

The LORD MAYOR announced the objects of the meeting. To a commercial mind it seemed that these objects were just, and that the public should have in the time of sickness a list of competent nurses to choose from, and to know that in doing so they were selecting persons who had been properly certified as nurses. He failed to see what objections could be urged against the granting of the Charter sought for by the Association. The Association was seeking to place its nurses on a par with other professions—the medical profession, for instance—as to proficiency in their particular calling.

Sir WM. SAVORY moved: "That this meeting is of opinion that the Royal British Nurses' Association, which already includes one-fifth of the whole number of trained nurses estimated to be at work in this country, is eminently worthy of public support and of incorporation by Royal Charter, and this meeting considers that the Association is well qualified to carry out the system of registration of trained nurses which it has commenced as a voluntary measure, and that, when fully carried out, this system will fully protect the sick against untrained and untrustworthy workers, to be of great assistance to medical men, and be most beneficial to trained nurses by furnishing easily obtainable information as to the education and experience which each registered nurse has received." He said that nurses were now in a position to claim the power of coöperating for mutual help and general advancement, and the public should insist upon a charter being granted for such purposes and for their own security. He knew of no objections to it which did not resolve themselves into misrepresentation or jealousy. The question, however, was a larger one and belonged to the people.

Sir JAMES CRICHTON BROWNE, in seconding the resolution, referred to the valuable lives that good nursing had saved during the recent epidemic of influenza as a reason,

Digitized by Google

why the nurses themselves should secure the benefits of their federation. These benefits must accrue if the public had facilities for distinguishing between efficient and skilled nurses and those who were nurses only in name and perhaps in uniform, but who had no practical or intelligent acquaintance with the technique of the sick room.

Mr. BRUDENELL CARTER said that the resolution before the meeting asked them to affirm that when fully carried out the system of registration would protect the sick against untrustworthy nurses. These words had been inserted after grave deliberation on the part of the Council. They expressed the conviction that in existing circumstances the sick were liable to have foisted upon them the services of people who, whatever might be their good intentions, were from sheer ignorance absolutely untrustworthy as nurses, and committed the gravest errors in the discharge of the duties which they ventured to undertake. The knowledge of the small proportion of their own earnings which went into the pockets of many nurses first excited his interest in this Association. It had become public information, in consequence of the evidence before Lord Sandhurst's Committee, that at least one of the hospitals in London had been making a profit by sending out imperfectly trained and unskilled women in the name of nurses, and so long as the authorities of any hospital were found to do that, one could hardly wonder that private speculators should endeavour to surpass them at their own game. The publication of the Register provided a real protection against a very real danger.

Dr. BEZLY THORNE explained the nature of the Register, and traversed in detail the objections which had been urged against it. Good nursing, he said, meant the unlearning of habits of half a lifetime and the acquirement of other habits which should be deeply ingrained for the rest of life—habits of order, method, kindness, gentleness, refinement, patience, self-abnegation, and powers of observation; but, above all, the faculty to exercise a wise though limited discretion. These habits could not be acquired by forcing, and consequently the Association required evidence of three years' training before admission to the register could be obtained.

The motion was then put to the meeting by the LORD MAYOR and carried unanimously.

On the motion of Sir DYCE DUCKWORTH, seconded by Dr. PAVY, a resolution was passed tendering the grateful thanks of the meeting to her Royal Highness the Princess Christian "for her great and steadfast exertions to bring about reforms in the nursing profession."

Sir HENRY THOMPSON proposed a vote of thanks to the Lord Mayor for presiding. It was no mean advantage to obtain the aid and advocacy of the head of this great city for a movement of this kind, and the meeting offered him their grateful thanks for his kindness.

The vote, having been seconded by Dr. PRIESTLEY, was agreed to, and the meeting terminated.

THE IRISH MEDICAL SCHOOLS' AND GRADUATES' ASSOCIATION.

THE annual general meeting of this Association was held at 11, Chandos-street, W., on March 17th. In the absence of the president the chair was taken by Dr. Macnaughton Jones. The annual report was read, and, with the balance-sheet, unanimously adopted. The officers for the ensuing year were elected. The annual dinner of the Association afterwards took place in the large room at the Holborn Restaurant. Director-General Dick, C.B., R.N., the new president, was in the chair, and eighty-nine members and guests attended, including several ladies. The Association guests were Sir George Stokes, F.R.S., and Rear-Admiral Colomb. The proceedings were enlivened by an excellent programme of music.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6136 births and 4848 deaths were registered during the week ending March 19th. The annual rate of mortality in these towns, which had been 20·5 and 22·9 per 1000 in the preceding two weeks, further rose last week to 24·8. In London the rate was 24·3 per 1000, while it averaged 25·2 in the thirty-two provincial towns. The lowest rates in these towns were 13·8 in Croydon, 15·6 in West Ham, 15·7 in Brighton, and 17·4 in Newcastle-upon-Tyne; the highest rates were 32·5 in Wolverhampton, 32·7 in Bolton, 33·2 in Salford, 33·1 in Liverpool, and 33·4 in Oldham and in Burnley. The 4848 deaths included 477 which were referred to the principal zymotic diseases, against 390 and 406 in the preceding two weeks; of these, 196 resulted from whooping-cough, 146 from measles, 51 from diphtheria, 36 from diarrhœa, 24 from "fever" (principally enteric), 22 from scarlet fever, and 2 from small-pox. The lowest death-rates from these diseases were recorded in West Ham, Norwich, Portsmouth, and Plymouth, while they caused the highest rates in Sheffield, Salford, Birkenhead, Liverpool, and Wolverhampton. The greatest mortality from measles occurred in Huddersfield, Birmingham, Halifax, Birkenhead, Liverpool, and Wolverhampton; from whooping-cough in Sheffield, Salford, Derby, Bristol, Bolton, and Wolverhampton; and from diarrhœa in Blackburn. The mortality from scarlet fever and from "fever" showed no marked excess in any of the thirty-three large towns. The 51 deaths from diphtheria included 31 in London, 5 in Manchester, 2 in Leeds, 2 in Sheffield, and 2 in Hull. Small-pox caused 2 deaths last week in London, but not one in any of the provincial towns; 16 small-pox patients were under treatment in the Metropolitan Asylum Hospitals, and 1 in the Highgate Small-pox Hospital on Saturday last. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of last week was 1230, against 1190 and 1202 on the preceding two Saturdays; 146 new cases were admitted during the week, against 96 and 117 in the previous two weeks. The deaths referred to diseases of the respiratory organs in London, which had been 379 and 454 in the preceding two weeks, further rose last week to 523, but were 10 below the average. The causes of 115, or 2·4 per cent., of the deaths in the thirty-three towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Croydon, Bristol, Preston, Sunderland, and in six other smaller towns; the largest proportions of uncertified deaths were registered in West Ham, Halifax, Sheffield, and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 22·5 and 22·6 per 1000 in the preceding two weeks, further rose to 24·2 during the week ending March 19th, but was 0·6 below the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 14·1 in Dundee and 15·5 in Perth to 23·9 in Greenock and 28·8 in Glasgow. The 675 deaths in these towns included 28 which were referred to whooping-cough, 15 to measles, 12 to diarrhœa, 7 to scarlet fever, 5 to diphtheria, 4 to "fever," and not one to small-pox. In all, 71 deaths resulted from these principal zymotic diseases, against numbers increasing from 62 to 70 in the preceding three weeks. These 71 deaths were equal to an annual rate of 2·6 per 1000, which slightly exceeded the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of whooping-cough, which had been 19 and 29 in the preceding two weeks, were 28 last week, of which 15 occurred in Glasgow, 4 in Edinburgh, and 4 in Aberdeen. The 15 deaths from measles were within one of the number in the previous week, and included 13 in Glasgow and 2 in Edinburgh. The 12 fatal cases of diarrhœa showed a further increase upon recent weekly numbers; 6 occurred in Edinburgh and 4 in Glasgow. The deaths from scarlet fever, which had been 4 and 3 in the preceding two weeks, rose again to 7 last week, of which 5 occurred in Glasgow, where 3 of the 5 deaths from diphtheria were also recorded. The deaths referred to diseases of the respiratory organs in these towns, which had been 155 and 154 in the preceding two weeks, increased last week to 183, but were 11 below the number in the corresponding week of last year. The causes of 73, or nearly 11 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 32·7 and 35·5 per 1000 in the preceding two weeks, further rose

Digitized by Google

to 36·8 during the week ending March 19th. During the past eleven weeks of the current quarter the death-rate in the city averaged 38·3 per 1000, the rate for the same period being 29·4 in London and 19·9 in Edinburgh. The 247 deaths in Dublin during the week under notice showed an increase of 9 upon the number in the preceding week, and included 12 which were referred to measles, 5 to whooping-cough, 3 to "fever," 2 to scarlet fever, 2 to diarrhœa, but not one either to small-pox or diphtheria. In all, 24 deaths resulted from these principal zymotic diseases, equal to an annual rate of 3·6 per 1000, the zymotic death-rate during the same period being 2·9 in London and 2·8 in Edinburgh. The fatal cases of measles, which had been 7 and 12 in the preceding two weeks, were again 12 last week. The deaths referred to whooping-cough, which had been 8 and 6 in the previous two weeks, further declined to 5 last week. The 2 fatal cases of diarrhœa corresponded with the number in each of the preceding three weeks. The 247 deaths in Dublin last week included 34 of infants under one year of age, and 63 of persons aged upwards of sixty years; the deaths of infants corresponded with those recorded in the previous week, while those of elderly persons showed a slight decline. Four inquest cases and 3 deaths from violence were registered; and 79, or nearly a third, of the deaths occurred in public institutions. The causes of 19, or nearly 8 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

THE death is announced *from Bombay* of Staff-Surgeon John Mackie, aged forty-two, of H.M.S. *Boadicea*. His death was considered to be mainly due to the severe strain he had recently undergone owing to the large amount of sickness that had prevailed on board the flagship. The deceased served on board the *Briton* during the Soudan Expedition of 1884–85, obtaining the Egyptian medal for his services.

Surgeon-Major T. J. Gallwey has been selected by the Commander-in-Chief for employment with the Khedive's Army, and he has been ordered to leave for Egypt at once.

Surgeon-Lieutenant-Colonel A. S. Lethbridge, M.D., C.S.I., Inspector-General of Gaols, Bengal, succeeds Colonel Henderson as General Superintendent of Operations for the suppression of Thuggi and Dacoity.

Surgeon-Captain W. G. A. Bedford has been appointed Adjutant of the depôt and training school Medical Staff Corps, Aldershot, from the 9th inst., vice Surgeon-Captain G. E. Twiss, who has embarked for service at Malta.

ARMY MEDICAL STAFF.—Brigade-Surgeon-Lieutenant-Colonel W. D. Wilson, in medical charge of the Station Hospital at Colaba, has been transferred to the charge of the Station Hospital at Kurrachee, vice Brigade-Surgeon-Lieutenant-Colonel J. M'D. O'Farrell, tour expired.—Surgeon-Lieutenant-Colonel F. Lyons is to take charge of the Hospital at Colaba.—Surgeon-Major R. H. Quill has handed over the charge of the Station Hospital, *Deolali*, to Surgeon-Lieutenant-Colonel J. D. Edge, on transfer to general duty in the Bombay District.—Surgeon-Major A. L. Browne, Bombay command, has been appointed to the medical charge of the Station Hospital, Mhow.—Surgeon-Captain J. D. Moir has been appointed to the Brigade of Foot Guards for duty.—Surgeon-Lieutenant-Colonel J. G. Williamson has been struck off the strength of the Straits Settlement command on returning to England, tour expired.—Surgeon-Major-General William Arthur Thomson, M.B., is placed on retired pay (dated March 10th, 1892).—The undermentioned Surgeon-Captains to be Surgeon-Majors (dated March 6th, 1892):—Frederick Rowland Barker, M.B.; Alfred Keogh, M.D.; Charles Birnie Hill; James Richardson Andrew Clark, F.R.C.S. Edin.; Henry James Michael; Thomas Dorman, M.D.; Arthur Walter Patrick Inman, M.B.; Thos. Martin Corker, M.D.; Edmond Henry Myles, M.B.; Thomas Beattie Moffitt; Chas. Alfred Webb; Henry Martin, M.B.; Arthur England Johnson Croly, F.R.C.S.I.; Robert Oriel Cusack; Ernest Frederic Smith; William Daniel Amherst Cowen; Robert Hall Forman, M.B.; Samuel James Flood, F.R.C.S. Edin.; Geo. Winsor Robinson; John Watson, M.D.; Octavius Todd, M.B.; Alfred Osmond Geoghegan, M.D.; James Dunne Day, M.B., F.F.P.S. Glasg.; Arthur Maher Kavanagh; John Gasson Harwood, F.R.C.S. Edin.; Robert Dickie Donaldson, M.D.; Henry Lawrence Esmonde White; Arthur Hyde Barlton; Edward North, F.R.C.S. Edin.; George Frederick Poynder; George Frederick Alexander Smythe, F.R.C.S. Edin.; Henry Lewis Battersby; Augustus Hewett, F.R.C.S. Edin.; Peter Mulvany; James Edward Nicholson; William Owen Wolseley; Thomas Frederick MacNeece; Benjamin Thomas M'Creery, M.B., F.R.C.S.I.; Arthur Patrick O'Connor, F.R.C.S.I.; James M'Mullen Bolster, F.R.C.S.I.; Douglas Wardrop, M.B.; Geo. Taylor Goggin; John Matthew Jones; Fausset Maher Baker, M.B.; Alfred Asbury, F.R.C.S.I.; Patrick Maurice Carleton, M.D.; Fitzroy Beresford Maclean; Raglan Wykeham Barnes; and Patrick Halion Fox, F.R.C.S.I.

ARMY MEDICAL RESERVE OF OFFICERS.—Surgeon-Lieutenant-Colonel Charles Arthur Patten, 2nd Volunteer Battalion, the Duke of Cambridge's Own (Middlesex Regiment), to be Surgeon-Lieutenant-Colonel (dated March 23rd, 1892).

NAVAL MEDICAL SERVICE.—The following appointments have been made at the Admiralty:—Surgeons: A. G. W. Bowen, B.A., M.B., to Plymouth Hospital (dated March 23rd, 1892); Richard L. Price, M.B., to the *Pembroke*, and Montague L. B. Rodd, to the *Vivid*, additional, for disposal (both dated March 29th, 1892); Herbert L. Penny, to the *Excellent*, additional, for disposal (dated April 8th, 1892); and Arthur E. Kelsey, B.A., M.B., to the *Pembroke*, additional, for disposal (dated April 1st, 1892).

VOLUNTEER CORPS.—*Light Horse:* 1st Roxburgh (Border) Mounted Rifle: Surgeon-Lieutenant-Colonel P. Kynoch (Brigade-Surgeon-Lieutenant-Colonel) resigns his commission; also is permitted to retain his rank, and to continue to wear the uniform of the Corps on his retirement.—*Artillery:* 1st Renfrew and Dumbarton: Surgeon-Major J. W. Taylor, M.D., to be Surgeon-Lieutenant-Colonel (dated March 23rd, 1892).—*Rifle:* 1st Volunteer Battalion, the East Yorkshire Regiment: Surgeon-Captain R. Hagyard resigns his commission (dated March 19th, 1892).—2nd (Hertfordshire) Volunteer Battalion, the Bedfordshire Regiment: The undermentioned Honorary Assistant Surgeons resign their commissions:—S. B. Farr and F. R. Webster (both dated March 19th, 1892).—5th Volunteer Battalion, the Cheshire Regiment: Surgeon-Captain W. R. Dambrill-Davies to be Surgeon-Major (dated March 19th, 1892).—1st (Pembrokeshire) Volunteer Battalion, the Welsh Regiment: Surgeon-Major E. P. Phillips to be Surgeon-Lieutenant-Colonel who resigns his commission; and to be permitted to retain his rank, and to continue to wear the uniform of the Battalion on his retirement (dated March 19th, 1892).—1st (Hallamshire) Volunteer Battalion, the York and Lancaster Regiment: Surgeon-Major A. Hallam resigns his commission; also is permitted to retain his rank, and to continue to wear the uniform of the Battalion on his retirement (dated March 19th, 1892).

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—The annual meeting of governors was held in the Bell Medical Library and Institute on Tuesday, the 8th inst. The total number of patients treated during the year was 16,133. The number of in-patients has been 2168. Of these, 895 were medical and 1273 were surgical cases; 1531, as accidents or urgent cases, were admitted without tickets. The total number of out-patients has been 13 965, showing an increase of 936 as compared with the previous year. Of these, 6636 were treated without tickets, being accidents or urgent cases. The income for the past year amounted to £7465 19*s.* 2*d.*, being a decrease of £88 3*s.* as compared with the previous year. The donations show a decrease of £234 5*s.* 1*d.*; but it is very gratifying to find an increase in the Hospital Saturday collections of £173 15*s.* 5*d.* The total expenditure for the past year has amounted to £7751 6*s.* 8*d.*, showing an increase of £159 16*s.* 2*d.* On the suggestion of the Hospital Saturday committee it has been decided to purchase a horse ambulance and a manual ambulance, which will always be in readiness at the hospital for the conveyance of accidents from any part of the town or district to the institution. The want of increased sanitary accommodation in connexion with the female wards, and also additional rooms for the nurses, having occupied the careful attention of the board for some years past, plans were obtained for building an additional storey over the out-patient department, and the work, which is nearly completed, will provide five additional rooms, besides three bath rooms, lavatories, and necessary offices.

"Audi alteram partem."

COMPARATIVE ACTION OF THE DIFFERENT BRANDS OF CHLOROFORM.

To the Editors of THE LANCET.

SIRS,—The above research was prompted by the records in recent medical journals of deaths during anæsthesia. We believed that differently manufactured chloroform, although conforming to the tests required by the British Pharmacopœia, might have different actions, and that possibly some of the dangers were due to the use of impure chloroform. We determined to test this assumption by administering chloroform to guinea-pigs. The same animals were put under the influence of the brands (subsequently referred to) on different days, as only in this way, we considered, could a careful comparative estimate of their action in each case be satisfactorily ascertained. We therefore obtained samples of: (1) Pictet's chloroform medicinale; (2) Duncan, Flockhart, and Company's, made from pure alcohol; (3) Macfarlan and Company's chloroform. pur., prepared with rectified spirit; (4) Macfarlan and Company's chloroform. pur.; (5) Duncan, Flockhart, and Company's "blue brand"; (6) Warrington Chemical Company's chloroform. The usual method of administering the vapour on a piece of blotting-paper under a bell jar was followed, the quantity in each case being thirty minims. We then noted (1) what difference there was in regard to the time of inducing anæsthesia; (2) the time when respiration ceased; (3) the time of recovery after artificial respiration—i.e., when the animal was able to move about easily; (4) any other differences.

The following average results were obtained:—

—	Anæsthesia.	Respiration ceased.	Recovery.	Remarks.
	M. S.	M. S.	M. S.	
1. Pictet's Chloroform Medicinale	4 20·0	1 36·6	7 40	No tremors
2. Duncan, Flockhart, and Co.'s, from pure alcohol	4 21·6	1 13·33	8 50	No tremors
3. Macfarlan and Co.'s Chloroform. Pur., prepared with rectified spirit	5 8·0	1 50·0	12 36	Rhythmic tremors distinct
4. Macfarlan and Co.'s Chloroform. Pur...	4 57·0	1 26·0	11 48	Rhythmic tremors distinct
5. Duncan, Flockhart, & Co.'s Blue Brand	3 59·3	4 43·3	18 20	Rhythmic tremors pronounced
6. Warrington Chem. Co.'s Chloroform..	3 55·0	2 0·0	13 20	Rhythmic tremors pronounced

The conclusions from this research, so far as it goes, show that there is a very evident difference of action exhibited by chloroforms of different manufacture. Thus, with the first two brands (Pictet's and Duncan, Flockhart, and Co.'s) recovery was quicker than with the other four; and further, during recovery no rhythmic tremors were observed. We may therefore assume that these latter brands contain some substance or substances extraneous to pure chloroform. What the nature of this substance or these substances may be we cannot at present determine. At our suggestion Mr. Tatlock, City Analyst for Glasgow, has kindly undertaken to make an exhaustive chemical examination of the different brands. On the completion of the inquiry we shall give the results. The research is by no means completed, but we deem it advisable to place before the profession the results of this preliminary inquiry. At as early a date as possible we shall make a fuller statement, and give details of the experiments and the action of different brands of chloroform. It may be mentioned that our observations are entirely in correspondence with those of the recent Hyderabad Commission—viz., that the heart continues to beat after respiration has ceased.—We are, Sirs, yours truly,

M. CHARTERIS, M.D.,
Prof. Mat. Med. and Therapeutics, Glasgow Univ.;
WM. MACLENNAN, M.B.,
Assistant to Prof. Mat. Med. and Therapeutics, Glasgow.
The University, Glasgow, March 19th, 1892.

THE SPREAD OF LEPROSY.

To the Editors of THE LANCET.

SIRS,—Since reading the valuable paper by Dr. Thin "On the Origin and Spread of Leprosy &c.," which appears in THE LANCET of Jan. 16th, I have on several occasions thought that the following account of an instance which occurred in my experience might not be uninteresting. Some twelve years ago, whilst I was resident surgeon of the Colonial Hospital in Georgetown, British Guiana, the females and children of the Mahaica Leper Asylum were transferred to a building some distance from the hospital. The house in which these lepers were placed was situated—an unavoidable condition owing to circumstances—about thirty yards to the windward side of a house occupied by one of the married attendants of the institution. This man had a family of five children, all of whom I knew, and can answer for the fact that they were healthy children at that time, ranging from five to fifteen years. The lepers remained there whilst other quarters were being prepared for them—for several years in all. Notwithstanding every precaution there was a certain amount of covert intercourse between the children of the parties above referred to, and now one of the children of the attendant has developed for some years past the disease. As regards the parents of this child, they are both immigrants of the colony, without any symptoms of leprosy; the father a white man from Madeira, the mother an Englishwoman. To what, then, must we attribute this development of the disease—contagion or coincidence? Whatever convictions resulting from experience may be held by other persons, I must say that the case I now record is, in my opinion, very strong evidence of there having been some contagious influence at work, and it supports me in what I tried to make understood when I had any dealings with lepers—that it is a disease which is slowly contagious under certain conditions of environment and individual idiosyncrasy. It is contagious not in the same way as we understand this expression when applied to such diseases as the exanthemata, but slowly, in such manner as it is now held that phthisis pulmonalis is contagious. Such a case as that which I have recorded above could, I know, be swamped by instances of persons who, through long exposure to, and intimate relationship with, leprotic influences and persons, had remained unaffected; yet such would only be negative evidence, and, indeed, might be pointed to in any disease—markedly phthisis. Yet I doubt if any medical man maintains that this latter disease is incapable of being bestowed in course of time by the diseased on those who may not actually be consumptive, but who are in a condition of "physiological misery" rendering them hotbeds for the germination of the provoking cause of such disease. Similarly I believe in an individual idiosyncrasy as a very potent factor assisting the contagium of leprosy, for we often notice that only one or two members of a family develop the disease whereof all were subjected to the same morbific influence, and it is this individual vulnerability which gives the disease a foothold, as it were, in such suscepts constitution when exposed for any length of time to leprous influences. Such influences can undoubtedly be combated by sanitary and hygienic improvements, as may all the diseases which flesh is heir to; but it would be a somewhat ideal condition of things which would render such baneful influences inoperative, and till such condition is reached it is imprudent that the two classes, the leprous and the non-leprous, should be permitted to co-mingle for any length of time.

I am, Sirs, yours faithfully,

London, March 10th, 1892. C. E. MACNAMARA.

POST-MORTEM APPEARANCES OF THE BRAIN IN INFLUENZA PATIENTS.

To the Editors of THE LANCET.

SIRS,—As the above subject is now being discussed in THE LANCET, perhaps I may be allowed to say a few words, having, with my colleagues, during the first two months of this year had exceptional opportunities for examining the brains of those dying from the complications following influenza, for I am sorry to say we lost a large number of our very old patients from secondary pneumonia. On referring to the notes made at the time, I find that in a large number of the cases there was marked congestion of the pia mater recorded both by Dr. Ewart and myself. This was to an extent unusual, as seen in the brain of the insane. The engorgement of the vessels was most marked at the upper surface and sides, and in many instances it was very slight at the base. This condition existed in 55 per cent. of our cases. Usually only the larger vessels were distended, but in one of my cases there was intense injection of the minute capillaries over the surface of the convolutions, especially at the upper part of the cerebrum, and comparatively little at the base. The congested state of the pia mater extended down over the medulla and spinal cord, but in no other of my cases was this so. In this case also there existed a deeply congested false dura mater, which in places could be easily peeled off the under surface of the true one, whilst in others it was firmly adherent. The vessels in the dura mater, contrary to what was usually found, were in this case much congested; in only one other of mine was this noticed. In another brain, the vessels over one cerebral hemisphere only were engorged with blood; on the other, the right, they were empty and the brain was anæmic. In this case, however, the right vertebral artery was extremely small.

Dr. Ewart, who kindly allows me to mention his cases, states that in one of them the venous sinuses at the base were much engorged. In another, "the vessels, especially the veins of the pia mater, were loaded with blood, the dura mater vascular, and a clot existed on its outer surface, the diplocic tissue was engorged": and in a third case "after removal of the pia mater (which was congested) the convolutions of the upper surface were seen punctated with vascular points. There was no abnormal appearance of the membranes or vessels at the base." In very few of our cases was the engorgment of the vessels at the base noticed to the extent referred to by Dr. Althaus, and beyond what has been stated, there was no other morbid condition present that could in any way be said to be dependent on either influenza or pneumonia. Other lesions of the brain invariably existed, but were such as are common to those dying in lunatic asylums. In not one of our cases was there any actual inflammation of the membranes present. I am inclined to agree with Dr. Goodall that the majority of the cases first brought forward showed lesions probably unassociated with influenza; but whether the hyperæmia of the pia mater, so often found, is dependent on the secondary pneumonia, or owes its origin to the primary disease, is not easy to prove, although I do not believe there is any doubt that simple pneumonia may give rise to a congested state of the membranes. My colleague, Mr. R. Rouse, however, informs me that in a certain number of the brains of male patients examined by him he found, in addition to an intense congestion of the membranes, an actual deposit of recent lymph on the pio arachnoid, which could be stripped off with ease. This existed in three out of about eight cases examined. He has, moreover, seen actual purulent cerebro-spinal fluid present in a patient who died from influenza, and he is firmly convinced himself that a cerebro-spinal meningitis existed in these cases, and perhaps is always present with influenza. This may be said to be evidence in favour of Dr. Althaus' view of the nature of the so-called influenza.

I am, Sirs, yours faithfully,

CECIL F. BEADLES,
Assistant Medical Officer.

Colney Hatch Asylum, March 15th, 1892.

To the Editors of THE LANCET.

SIRS,—In concluding my share in the communications made in THE LANCET upon this subject, I should like to correct an accidental misrepresentation made by Dr. Althaus in his somewhat limited advocacy of the significance of the cases quoted by him. It is stated that I suggest that hæmorrhage into and softening of the cerebellum in a healthy patient aged twenty-five might be due to sneezing and coughing. I need only remark that at the time I wrote there was no means of knowing the patient's state of health or age, since neither was mentioned in Dr. Althaus' communication. This "startling suggestion" cannot, therefore, be attributed to me.—I am, Sirs, yours faithfully,

EDWIN GOODALL, M.D. Lond.

West Riding Asylum, March 20th, 1892.

THE ASSOCIATION OF MEMBERS OF THE ROYAL COLLEGE OF SURGEONS.

To the Editors of THE LANCET.

SIRS,—I fully endorse all that Mr. Jabez Hogg has said regarding the unwavering support which THE LANCET has always given to all efforts in the direction of reform at the College of Surgeons. With regard to his allusion to the difference of opinion which has existed as to the advisability of the legal proceedings now terminated, I should like to draw attention to a point which has not received sufficient notice. The Members have been agitating for the acquisition of certain changes in their relations to the government of the College, which they believed would be of advantage, not to themselves as individuals, but to the corporation as a whole. During the course of their agitation they were advised by the counsel who represented them in their application to the Privy Council, in opposition to the new Charter, and who therefore presumably had special knowledge of the subject, that they had already certain legal rights which had fallen into abeyance, but which could be revived by being exercised. Upon this advice the committee had obviously no alternative but to obtain a legal decision, when the attempt to exercise one of these alleged rights was forcibly resisted. I am bound to add, however, that the majority of the committee would have been much better pleased if the action could, by arrangement with the Council, have been made a "friendly" one.

I am, Sirs, yours faithfully,

Southfields, S.W., March 21st, 1892. W. G. DICKINSON.

MEDICAL AND LEGAL CORONERS.

To the Editors of THE LANCET.

SIRS,—Allow me to thank you for your favourable notice of my paper, and to point out two errors into which I have inadvertently fallen. The first is on page 8, in which I have led it to be inferred that Mr. Oliver Pemberton, the coroner for Birmingham, is debarred from practice. This is not correct. The other is in a footnote on the same page. Instead of the "Coroners Act, 1887," it should be the "Municipal Corporations Act." A very slight alteration in this latter would enable any physician or surgeon to act as deputy coroner as well as coroner in any municipal corporation or city, and I live in hopes that this will be effected.

I have posted copies of my paper to every English and Welsh medical coroner, but have received only two acknowledgments of their receipt. Should any have miscarried, I will send another.—I am, Sirs, yours faithfully,

Liverpool, March 19th, 1892. FRED. W. LOWNDES.

P.S.—A physician or surgeon can be deputy to a county coroner.

*** We inadvertently omitted to give the name of the publishers of Mr. Lowndes' pamphlet—Messrs. Churchill, New Burlington-street.—ED. L.

To the Editors of THE LANCET.

SIRS,—I was much interested in reading the leading article in the last issue of THE LANCET concerning the office of coroner, and who are the best persons to hold the post. I wish to draw the attention of the medical profession to the fact that the Bill that was read a first time in the House of Commons a few weeks ago to amend the Coroners Act of 1887 does not propose to alter the clause relating to the appointment of "deputy coroner." With regard to large towns such as Bristol, the Act of 1887 says "that the office of coroner may be held by any fit and proper person &c." And the

Digitized by Google

same Act goes on to say that "the coroner may appoint a deputy &c.," but that such person must be either a "barrister or solicitor." I conclude from this that in the large cities the "coroner" may be a medical man, but that the "deputy coroner" may not. It is clear from this that when the office of coroner becomes vacant only barristers or solicitors can claim to have acted as deputy, and they are therefore usually elected to the coronership. I think that if our profession wish to see more medical men holding the office of coroner in large towns, we ought to get the clause relating to the appointment of the coroner's deputy altered, and now is the time to do it.

I am, Sirs, yours truly,

J. PAUL BUSH,
Surgeon to the Bristol Royal Infirmary and Bristol Police Force.

Clifton, Bristol, March 22nd, 1892.

*** We would call the attention of Mr. Bush to the postscript of Mr. Lowndes' letter.—ED. L.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

An Incorrigible Young Criminal.

AT the last assizes two boys, aged respectively nine and eight, were tried for the wilful murder of a boy about the same age. A leading article appeared in THE LANCET of Jan. 2nd last dealing exhaustively with the main feature of the case—the responsibility of such young criminals. The jury found a verdict of guilty, but with a rider to their verdict which caused the learned judge (Justice Lawrance) to order the immediate discharge of both prisoners. Subsequently the Rev. Father Nugent, the well-known philanthropist, offered to receive the boys, who are Roman Catholics, into his Boys' Refuge. While it is very satisfactory to be able to state that one of the boys is behaving admirably in his new home, it is equally sad to note that his companion has again appeared before the stipendiary magistrate. A policeman found him lying in a water-closet at an early hour of the morning, and locked him up. The governor of the Boys' Refuge described the prisoner as unmanageable, and that he had absconded four times. He was remanded.

An Intramural Cemetery.

St. James's Cemetery is situated almost in the centre of the city, and close to the streets where many of the local faculty reside. It was first opened in 1829, on the site of a stone quarry, and most of the ground used for interment is at a very considerable depth below the level of the adjoining streets. The enclosed space comprises 44,000 square yards of land, which is mostly red sandstone, dry, and suitable for burial purposes; though it is stated that in some parts the graves are full of water. Some years ago an inquiry was held by the late Mr. Holland; this was subsequent to the year 1854, when most intramural burial grounds were closed by Order in Council, though this cemetery was not closed. At this inquiry it was shown that the burials in public graves were not conducted satisfactorily, and these were prohibited by Order in Council on Mr. Holland's report. Since then the burials have been mostly of the bodies of those belonging to the upper and middle classes of society, averaging in recent years 500 annually. Some of those who reside near hoped that the recent death of the Rev. William Banister, who had been resident chaplain since 1851, would have led to the closing of the cemetery; but a reverend gentleman has been appointed to succeed him, and the cemetery is still used, not only by those who are the owners of graves and vaults, but fresh ground, of which there still remains a very considerable portion, is still broken. A discussion is going on in a daily paper as to the propriety of continuing this burying-place in the midst of a large centre of population. Much can be said both in favour of and against its being closed. It is greatly to be wished that an inquiry will be ordered by the Home Secretary, so that both sides may be heard, and that a just decision may be made.

The Rainhill Tragedies

There was never a better illustration of the old saying that truth is stranger than fiction than the recent tragic discovery at Rainhill. Even with the proximity of a large county asylum and of a railway station at which many trains stop and more pass through, Rainhill has the appearance of a peaceful English village of the most model type, and it is hard to realise that such atrocious deeds could have been permitted in its midst. Some surprise has been expressed in medical circles that Mr. Brighouse, the county coroner, did not avail himself of the services of the lecturer on Medical Jurisprudence at the Liverpool University College, Mr. Paul having now acquired a considerable reputation in forensic medicine, and having given evidence in many important trials. It is only just, however, to the medical gentlemen called, Drs. MacLennan and Hutchinson, of Widnes, to say that the examinations of the bodies were made in a very complete and satisfactory manner, and that the evidence was given with great clearness.

An Epidemic of Violence.

From time to time crimes of violence, often taking the form of assaults upon the police, assume an epidemic form, and it is significant that Saturday and Sunday are the days specially selected for these displays. On Monday last the local stipendiary magistrate, Mr. W. J. Stewart, had a batch of five such cases, two being assaults on the police. The magistrate had noticed an increase of late in assaults on the police, and intimated plainly that he should punish severely such violence.

March 22nd.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

Tyne Port Sanitary Authority.

THE report of our able medical officer of health, Dr. H. E. Armstrong, has been presented to the Tyne sanitary authority, and shows that the total number of vessels inspected during the year was 11,513. Of these, 8702 were British. There were 9513 passed as in good sanitary condition, 1209 being passable, and 811 defective. The inspectors had visited 199,719 crews of vessels, passengers, and emigrants arriving in the Tyne. With the exception of three, all the vessels were found in good condition. Large consignments of herrings and other fish continued to come from Norway. No case of overcrowding passengers or crews had come under notice. The report is a record of an immense amount of work done and of good effected, and is creditable to all concerned in the inspection.

Carlisle: Silloth Convalescent Institution.

The twenty-ninth annual meeting of the Cumberland and Westmoreland Convalescent Institution at Silloth has been held at Carlisle, the mayor presiding. The results of the year's working had been most satisfactory; 641 patients had participated in the benefits of the institution, of whom 518 had gained weight during their stay. The financial statement was satisfactory, and a balance on the year's working was carried to the building account.

Sunderland Provident Dispensary.

The annual meeting of the Sunderland Provident Dispensary has been held, and the report records a very large amount of work, which is shown by the statement that 24,500 prescriptions had been dispensed, while the number of visits paid by the medical officers to patients at their own houses was 13,000. No less than 18,000 consultations had been given at the dispensary or at the medical officers' own houses. The financial statement was satisfactory, showing that, after paying the medical officer £600, a balance had been carried to the reserve or contingent funds. The committee is hopeful of obtaining within the next few years new and more commodious premises, centrally situated, to enable the Sunderland Dispensary to take its proper position amongst the public institutions of the town.

Sudden Death of Mr. John Davis, M.R.C.S.

The death of Mr. John Davis, surgeon, of Sunderland, is announced, which took place at his residence early on Saturday morning last. Mr. Davis, who was in his sixty-fourth year, leaves a grown-up family. He was much respected as a practitioner and a citizen, and filled many public offices at the time of his death. Mr. Davis was chairman of the board of guardians, and on the evening preceding his death attended a meeting of the house committee. He was, if I mistake not, a member of a well-known medical

Digitized by Google

family of that name, of Workington, near Gateshead, and of Low Fell. Mr. Davis's father was in his time the only surgeon in practice in the wide district between Gateshead and Durham city.

Bacteriological Laboratory.

In the course of his lecture last week on "Human Parasites" Mr. Page mentioned to the very large audience "that it was due to an eminent citizen of Newcastle, Mr. Clement Stephenson, and his investigations into the relationship of animals to man, that the College of Medicine at Newcastle had been recently able to establish within its walls a laboratory thoroughly equipped with the most modern appliances for the investigation of the many interesting problems constantly arising in this department of study." In addition to Mr. Stephenson's pecuniary aid it should not be forgotten, however, that Dr. Heath also gave powerful assistance and impetus to the establishment of a bacteriological laboratory in the Newcastle College of Medicine. I hope in some future notes to give you a fuller account of this department.

A Coroner and Jury on "Viewing the Body."

At Jarrow the other day, at the conclusion of an inquest, the foreman wished to express the feelings of the jury on the objectionable and useless rule of "viewing the body," and asked, on the part of the jury, to be allowed to sign a petition against it. The coroner, however, suggested it would be better to petition in favour of a Bill, now before the Legislature, dealing with the question of "viewing the body," and this suggestion was carried out.

Professor George Hare Philipson, M.D., D.C.L., F.R.C.P., has been elected President of the University of Durham College of Medicine, Newcastle.

I hear that measles are so prevalent at Blackhill, in the county of Durham, that it has been requisite to close the Benfieldside Board schools. St. Mary's Roman Catholic schools have been closed for some time owing to the same cause.

Dr. Jeaffreson has announced a course of lectures on "Diseases of the Eye" during the ensuing session at the Eye Infirmary; also two special lectures on the ocular defects of children, open to school masters and school mistresses and others having the charge of children. A course of sanitary lectures is also announced, under the auspices of the Sanitary Institute and the Corporation of Newcastle. At the close of these lectures an examination for inspectors will be held.

Newcastle-on-Tyne, March 23rd.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Dinner to Professor Haycraft.

ON Thursday of last week Professor Haycraft was entertained to dinner by a number of his friends in Edinburgh. Dr. James occupied the chair, and Mr. Cathcart, F.R.C.S., was croupier. About forty sat down to dinner. Dr. James, in proposing the health of their guest, referred in well-chosen and appreciative terms to the important work he had performed as a teacher of advanced physiology in the University, and to the value of his original researches, and said that the reason of their meeting that evening was to express their appreciation and admiration for Professor Haycraft and their regret at the severance of his connexion with the Edinburgh School of Medicine. The toast was received with great enthusiasm. Dr. Haycraft, after acknowledging it and thanking his friends for their kindness to him, spoke of the spirit in which scientific work ought to be prosecuted, and animadverted on the commercial spirit which tended to pervade both teachers and taught. Dr. Haycraft was presented with a gold watch as a memento of the occasion.

Health of Edinburgh.

The mortality last week was 107, making the death-rate 21 per 1000. Diseases of the chest accounted for 47 deaths, and zymotic diseases for 7, of which 4 were due to whooping-cough. The intimations for the week were: typhus fever, 2; typhoid fever, 1; diphtheria, 4; scarlatina, 24; and measles, 58.

Aberdeen City Hospital.

The Public Health Committee of the Town Council are understood to have completed arrangements for the removal of patients suffering from infectious diseases and the proper disposal of infected clothing. Some time ago the committee purchased a new ambulance in which patients could be carried with the least possible inconvenience; and the old ambulance, which was unsuitable for the purpose of conveying patients to and from the hospital, is now being used for the removal of infected clothing to the hospital for disinfection.

Health of Aberdeen.

During the past week the following cases of zymotic diseases were notified to the medical officer of health:—Scarlet fever, 9; typhoid fever, 4; diphtheria, 2; whooping-cough, 51; erpsipelas, 6. Three deaths from influenza were recorded by the registrars during the week. In his report for February, Dr. Hay, medical officer of health for the city, says that during the month 14 deaths were attributed to influenza, as against 41 in January, 21 in December, and 3 in November. In the fatal cases the duration of the disease was from three weeks to one or two months. The epidemic of scarlet fever continues to decline. Whooping-cough is still very prevalent; during the month 222 cases, with 21 deaths, were recorded. In January there were 239 cases, with 22 deaths. There were 7 cases of typhus fever, and they nearly all came from a single tenement in an east-end street.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

Abolition of Visiting Physicians to Irish Lunatic Asylums.

THE governors of the Cork District Asylum have forwarded to his Excellency the Lord-Lieutenant a resolution protesting against the proposal to remove the visiting physicians of Irish lunatic asylums, and it is probable that other boards of asylums will follow the same course.

Sir P. Dun's Hospital.

A ball in aid of the funds of this valuable charity will be given under the patronage of her Excellency the Countess of Zetland and other distinguished ladies, in the Leinster Hall, on the 30th inst.

University of Dublin Tercentenary.

The following is the programme of the Tercentenary Celebration which has been adopted by the Tercentenary committee:—Tuesday, July 5th, at 10 A.M., reception of guests and delegates by the provost in the Examination Hall; 11.30 A.M., commemoration service in St. Patrick's Cathedral, guests and delegates to attend in academic robes or official costume; 4 P.M., garden party in the Fellows' Garden; 9 P.M., performance of Tercentenary Ode by University Choral Society; 10 P.M., reception and ball in the Mansion House. Wednesday, July 6th, 12 noon, conferring of honorary degrees in the Examination Hall, Trinity College; 3 P.M., inauguration of the Graduates' Memorial; 7.30 P.M., Tercentenary Banquet in the Leinster Hall. Thursday, July 7th, 11 A.M., procession in academic costume from the Examination Hall to the Leinster Hall; 11.30 A.M., presentation of addresses by the delegates, Leinster Hall; 8 P.M., dramatic performance in the Gaiety Theatre, at which Sheridan's "Rivals" and a farce written for the occasion will be performed. Friday July 8th, 11 A.M., addresses to the students by certain of the University guests in the Examination Hall; 12.30, College races; 10 P.M., University ball, Leinster Hall.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Toxic Dyspnœa in Cardiac Affections.

AT a meeting of the Société Médicale des Hôpitaux, held on the 4th inst., M. Huchard read a paper on a Form of Dyspnœa—toxic dyspnœa—occurring in cardiac cases, which is scarcely alluded to by any author. It often happens that a patient affected with disease of the aortic valves is seized with a form of dyspnœa distinct from the mechanical difficulty of breathing ordinarily met with in cardiac disease, and characterised by its intensity and its paroxysmal nature, the attacks being provoked by the least effort, and

Digitized by Google

also occurring spontaneously in the night. Physical examination of the heart and lungs fails to account for these attacks, and the urine is free from albumen. M. Huchard ascribes the paroxysms to renal insufficiency, the kidneys being incapable of completely eliminating the toxines introduced into the system through the alimentary canal. This renal insufficiency is, according to this authority, an early and nearly constant symptom in arterial cardiopathies, even in the absence of albuminuria. In support of this etiological hypothesis M. Huchard adduces two proofs, one of a therapeutical and another of an experimental order. The exclusion from the diet of all articles yielding a supply of toxines—soups, meat, fish, preserved meats, rich cheeses, &c.—suffices to bring about the disappearance of the attacks, and they no longer recur if a rigid milk regimen be instituted. The urine of these patients (taken before any treatment had been commenced) injected into the veins of animals was found to have a urotoxic coefficient ranging from 0·273 to 0·370, a coefficient markedly inferior to the normal, which is 0·464 (Bouchard). In certain instances, however, when hepatic insufficiency complicates the case, the urine may become hypertoxic, the toxines normally destroyed by the (healthy) liver, passing through the kidneys. After a certain time this hypertoxicity irritates the renal tissue and induces albuminuria. The nocturnal character of the dyspnœa in this class of cases is explained by the fact that the elimination of poisons is more active at night than during the day. The treatment found effectual by M. Huchard is the institution of an exclusively milk diet or a period of from one to three days, the diet to be then modified by the addition of eggs, vegetables, and overcooked meat, all articles of food containing toxines to be rigidly prohibited. It will often be necessary to prescribe, in addition, intestinal disinfectants, such as salol, betol, naphthol, salicylate of bismuth, and, above all, benzo-naphthol. Hydrochloric acid benefits these patients. In the interval of the attacks, iodide of potassium—or, preferably, iodide of sodium—should be prescribed. M. Huchard states that his experience of the employment of bromide of potassium for the relief of the early toxic dyspnœa is a disappointing one, that drug failing to relieve it in the least.

Death from Rupture of the Thoracic Aorta in a Man of twenty years.

The rarity of this accident in so young a man entitles the details as given by M. Vibert[1] to the honour of a record in your columns. The patient was a medical student who at the age of one year had suffered from convulsions, and four years later had gone through an exceptionally severe attack of typhoid fever. Since that period of his existence his health had been apparently good, no suspicion of heart disease having ever been entertained. On Feb. 8th he returned to his lodgings well and cheerfully disposed. In the course of the night, however, he was seized with a very sharp pain over the liver, which was only partially relieved by bilious vomiting which supervened in the morning. At 6 P.M. on Feb. 9th the sharp pain reappeared, and one hour later the patient uttered two loud cries and fell back dead. Post mortem the two pleural cavities were found to contain blood, as much as 1800 grammes being collected from the right cavity. The pericardium contained a little clear fluid; no trace of tuberculosis was discovered in the lungs. The aorta was enclosed in a mass of coagulated blood, the removal of which brought to light two transverse tears in the walls of the vessel. The middle coat in the neighbourhood of the tears was in a state of degeneration. MM. Vibert and Brouardel are inclined to ascribe this structural change to the attack of enteric fever undergone fifteen years previously.

March 23rd.

[1] Soc. de Méd. Légale, March 14th, 1892.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The Fourteenth Balneologists' Congress.

THE first sitting of the Fourteenth Balneologists' Congress was held here on Friday, the 11th instant, Professor Liebreich in the chair. Dr. Weissenberg of Kolberg spoke on the treatment of nervous diseases of the stomach, and Dr. Boas and Professor Ewald commented on his remarks. Dr. Lassar of Berlin discussed the treatment of eczema by baths. Dr. Mayer of Karlsbad treated the question, "What standpoint must we now take in the light of experience in the treatment of diabetes mellitus?" In the discussion Dr. Gaus of Karlsbad referred to the dietetic treatment of Külz of Marburg. The second sitting was held on the 12th, Dr. Thilenius in the chair. Dr. Römpler of Görbersdorf spoke on the treatment of phthisis and Koch's method, severely criticising the latter. Dr. Goldschmidt of Reichenhall treated the initial symptoms of nervous asthma; Dr. Lindemann of Heligoland, the effect of sea water; and Dr. Groedel of Nauheim, the introduction of uniform rules for reporting analyses of spring water. The last sitting was held on the 13th, Professor Liebreich in the chair. Dr. Posner of Berlin spoke on the internal treatment of stone, Dr. Frey of Baden-Baden on the watering places of the Black Forest, Dr. Joseph of Landeck on the etiology of neurasthenia, and on the American viburnum. Dr. Saalfeld of Berlin discussed the treatment of skin diseases by baths, and Dr. Schubert of Reinerz, bloodletting in chlorosis, which he warmly recommended, emphatically contradicting the objection that the cures he had effected were due to other causes. The Congress was closed by a banquet.

Professor Credé.

Professor Carl Credé of Leipsic, who died last week, was a great benefactor of mankind, for it was he who introduced the simple method now universally practised of preventing blennorrhœa in new-born infants. He was also the inventor of a manipulation in delivery which bears his name (der Credésche Handgriff) The more important of his writings are "De Omphali Proptosi," "Clinical Lectures on Midwifery," "The Prussian Midwives and their Relation to the State and to Obstetrics," "The Prevention of Inflammation of the Eyes in New-born Infants," "Manual of Midwifery," and "Healthy and Sick Lying in Women." Along with Speigelberg and Gusserow, he edited the "Contributions to Midwifery." He was born in Berlin in 1819, was appointed professor in Leipsic in 1856, and taught there till 1887.

Death of Professor Küssner.

Professor Küssner of Halle died last week, aged only thirty-nine. The themes of his writings are the accidental cardiac murmurs, scarlatinal nephritis, tuberculosis of the tongue and of the soft palate, tuberculosis due to inoculation, leucocythæmia, congenital constriction of the aorta, cirrhosis of the liver, disseminated acute myelitis, aphasia and athetosis, wandering pneumonia, the affection of the vagus in tabes dorsalis, local dropsy of uncertain origin, &c. His only book, the "Manual of Acute Infectious Diseases," was written by him conjointly with Richard Pott.

New Medical Publications.

"The Causes of Disease and How to Combat Them," by Dr. Krocker; "Man, or How our Bodies are Framed and How our Organs Work," by Dr. Ebenhoech; "Man in Health and in Sickness," by Professor Bock (fifteenth, much enlarged, edition); "The Hygiene of the Internal Organs," by Paul Montegazza; "The Comfort of the Patient," by Dr. Martin Mendelsohn (second edition); "Two Hundred Eye-Benefactions in Words and Pictures," by Dr. Katz, oculist (second edition); "A Short Compendium of the Diseases of Children and their Treatment;" "The Influenza Epidemic of 1889-1892," by Dr. Jacob Wolff. "Women's Work in War," by R. Behrends-Wirth; "The Quarantine Station, El Tor," by Dr. Paul Kaufmann; "The Penetration of Steam into Objects to be Disinfected," by H. Duncker.

The private lecturer, Dr. Thierfelder, has been appointed to succeed Professor Erwin von Esmarch as keeper of the Hygienic Museum here. The title of Sanitätsrath (Sanitary Councillor) has been conferred on Dr. Arthur Hartmann, and on Drs. Schwerin, Karl Kniger, and Julius Lazarus.

March 22nd.

FOOTBALL CASUALTIES.—Whilst playing a match on Saturday, at Bath, a young man fractured his clavicle. During a match on the 17th instant, at Worksop, between Kiveton Park and North Staveley, in the semi-final Sheffield Minor Cup, a Kiveton forward met with a severe accident, and on medical examination it was found he had "fractured his jaw."

Obituary.

THEOPHILUS REDWOOD, Ph.D., F.C.S.

THE death of Dr. Theophilus Redwood removes from amongst us one whose fruitful labours have exerted an abiding influence on the progress of pharmaceutical science during the present century. He was born in the year 1806 in Boverton, in Glamorganshire. Somewhat prematurely he was placed as assistant in an apothecary's shop in Cardiff, where for a period of three years he had the advantage of a practical, though rough and ready, introduction to pharmacy—of a kind, however, which was not congenial to his tastes. The school of pharmacy whence he obtained his early scientific knowledge was in the shop of John Bell and Co., in Oxford-street, to whom by chance he received a letter of introduction in 1823 He was then seventeen years of age, and he proceeded through every stage of pharmacy with admirable prudence until he reached the position of head dispenser in that firm. In 1830 he started on his own account in Crawford-street. In 1841 Jacob Bell commenced the organisation of the Pharmaceutical Society, and found in Mr. Redwood a thoughtful, painstaking, wise, and unobtrusive supporter of the enterprise. Mr. Redwood became Professor of Pharmacy when the Society was formed in the year 1842. In 1844 Professor Redwood was made director of the chemical laboratories, and two years afterwards was appointed to the amalgamated chair of Chemistry and Pharmacy. He held the office of secretary to the Chemical Society in conjunction with Sir Benjamin Brodie, and afterwards with Professor Odling. He became treasurer in 1870. Regarding his literary career it is only necessary to recall that when, in 1854, the Royal College of Physicians applied to the Council of the Pharmaceutical Society for assistance in remodelling the London Pharmacopœia, and a committee was appointed to this end, Professor Redwood was chosen as honorary secretary. In the autumn of 1859 the work was transferred and put into the hands of the Medical Council, when not only the London, but the united Pharmacopœia of London, Edinburgh, and Dublin was ordered to be produced, under the name of the British Pharmacopœia. In 1865 Professor Redwood was appointed by the Medical Council to edit a new edition of the British Pharmacopœia, which appeared in 1867; the edition with addenda which appeared in 1874, and again the edition of 1885. We possess, therefore, an official work, issued under joint medical and pharmaceutical authority, simple in its mode of construction and free from the confusion incident to the occurrence of formulæ of varied strength but of identical nomenclature.

In 1840 Professor Redwood was joint editor with Dr. Mohr of Coblentz of a Manual of Practical Pharmacy founded on the German text. The first edition appeared in 1847, the second in 1848, and the last in 1857. In 1872 he abridged Pereira's classical work on Materia Medica. He acted also as sub-editor to the *Pharmaceutical Journal*. For some time he was a contributor to the columns of THE LANCET of valuable papers on the mode of preparation and the qualities of various pharmaceutical products, a specially noteworthy communication being that on Nitrous Acid. He was engaged by the Government in 1856 on the subject of fermentation with Professor Graham and Professor Hofmann. He was public analyst for the county of Middlesex, for the districts of Holborn and St. Giles, and for the borough of Luton. Professor Redwood was one who had lived long and brought much profit by his experience and observation to the branch of medical knowledge with which he chiefly occupied himself. By his colleagues he was much esteemed for his sagacity, quickness of apprehension, and cordiality, by authors and editors for his literary ability, and by the medical profession he will always be remembered as one of the pioneers of the progress which medical science has made between the periods of his birth in 1806 and of his death in 1892. Marvellous has that progress been, but incapable of restraint, because the active promoters of it were not dreamers only, but men ready for action when the advantage of their profession demanded it. No pains did they spare, no obstacle or opposition daunted them. Dr. Theophilus Redwood was among them a worker well worthy to be named.

F. G. REED, M.D. ST. AND., &c.

WE regret to announce the death, in his seventy-fifth year, of Dr. F. G. Reed, at his residence in Hertford-street, Mayfair. Dr. Reed was an articled pupil of the late Mr. Luke (three times President of the Royal College of Surgeons), and received his medical education at the London Hospital. He originally intended to pursue the career of a consulting surgeon, but subsequently settled at Hertford, where for many years he had a very extensive practice among the leading county families and all classes, and attained a social position rarely equalled by a member of the profession in those days. From 1843 to 1856 he was physician to the Hertfordshire County Infirmary, and on his retirement the governors and residents in the neighbourhood presented him with a handsome testimonial in token of their personal esteem and of their appreciation of his services. In 1847 he obtained the Fellowship of the Royal College of Surgeons by examination, and in 1849 the degree of M.D. St. Andrews. In 1857 Dr. Reed became M.R.C.P., and removed to Hertford-street by the advice of his intimate friends, Sir Benjamin Brodie and Sir Wm. Fergusson. Here his professional skill, cheerful, sympathetic manner, and geniality secured him a wide but select connexion, until ill-health compelled him to retire about fifteen years ago. Dr. Reed was for many years a member of the Athenæum and Union Clubs and a Fellow of the Royal Medical and Chirurgical Society. He had been in failing health for some years, but his last illness was of very short duration. In 1866 he married, and he leaves a widow, as well as a daughter, a son, and an only sister, whose grief will be shared by all who knew him. Dr. Reed had the satisfaction of knowing that his son, in whom he took an intense interest, had, after a distinguished career at Harrow, recently obtained a Science Exhibition and a Science Scholarship at Trinity College, Cambridge, and a First-class in the Natural Science Tripos of last year, when he took his degree of B.A.

MEDICAL TRIAL.

COURT OF APPEAL.

PARTRIDGE *v.* THE GENERAL MEDICAL COUNCIL.

(Before the Master of the Rolls, Lord Justice Fry, and Lord Justice Lopes.)

AN application was made by the plaintiff, H. F. Partridge, for judgment, or for a new trial on appeal, from the judgment of Mr. Justice Denman, who entered judgment for the defendants at the trial before him with a special jury without taking the opinion of the jury. The action was for a *mandamus* to compel the General Medical Council to restore the name of the plaintiff to the Dental Register, from which it had been removed for infamous conduct in a professional respect in the year 1886. Mr. Justice Matthew and Mr. Justice A. L. Smith had in the year 1887 granted a *mandamus*. The name was, however, again removed in November, 1887. It is in respect of this erasure that the present action was brought. Mr. Willis, Q.C., and Mr. A. Beddall appeared for the appellant, and submitted that there was evidence to go to a jury to show that the Council had not properly exercised their powers under the Act. Mr. R. T. Reid, Q.C., and Mr. Muir Mackenzie, for the respondents, were not called upon.

The Court dismissed the appeal.

The Master of the Rolls, in giving judgment, said:—

In this case a person, whom I shall call a professional man, has been summoned to appear before a body of which he has become a member. An Act of Parliament has authorised him to be put upon a certain register, and thereby he obtains certain position and benefits. This Act says that if this body, who are a domestic forum, should find him guilty of any infamous or disgraceful conduct in a professional respect, they have a right to strike him off the register. They have done this here. Some time ago the plaintiff brought an action against this body for maliciously striking off his name, and he failed. Now he brings an action partly for a *mandamus* and partly for damages. The greater part of the argument has been directed to the first part of that claim. There is really no evidence on which anyone can say these gentlemen were actuated by anything like malice. As to the action for a *mandamus*, all we have to see is whether the body against whom the *mandamus* is asked had jurisdiction to do what they have done. It has been alleged

Digitized by Google

there was no evidence before them which would give them jurisdiction. The Council were acting under Section 13 of the Dentists Act, 1878. The plaintiff had, on obtaining his diploma in Ireland, promised not to advertise while holding that diploma. That body considered that they should act fairly by each other, and ought not to advertise. Just as in our profession, where all are rivals against each other, a barrister is not allowed to advertise his superior talents or that he will do his advocacy cheaper. I think if he did so I should consider it such disgraceful conduct that he ought to be immediately disbarred. No one need become a member of the dental profession unless he desires it. I say the authorities—this domestic tribunal—have a right to determine if it is within reason whether the conduct is or is not disgraceful professional conduct. In Ireland the defendant had promised not to advertise, and, having given that promise, according to his own evidence, he had spent more than £10,000 in advertising. This is his admission, and he continued to advertise after he had received a warning from the college in Dublin. This must be evidence of disgraceful conduct in a professional respect, and ample evidence upon which the Council might exercise jurisdiction. A *mandamus* cannot therefore go to them; they are not a court, and no rules are binding on them. Under Section 15 a committee is appointed. Fault cannot be found with them unless you can show that what they have done is contrary to natural justice. I agree it is contrary to natural justice to impose a penalty without letting a man know the accusation and without giving him an opportunity to meet it. It is said the Council did not give the plaintiff notice; but this is frivolous in this case, for a letter was written to the plaintiff telling him that his case would be considered on a particular day, and asking him to send any written defence he might desire or to attend in person, or both. He declines to attend, and we are told his reason was that there was no dispute as to the facts. Another point has been taken. It is said there was one person who was accuser and judge; it is against natural justice that an accuser should be also the judge. He must be both accuser and judge, and it has been argued that Mr. Macnamara was both these in the present case. When you look at the facts no one can truly say he was the accuser. The rule of law is well laid down in "Leeson *v.* General Medical Council" (43 Ch. D., at p. 384), as follows: "It must be in all cases a question of substance and of fact whether one of the judges has in truth also been an accuser." That is to distinguish it from mere technicalities. There is no evidence here that in fact Mr. Macnamara authorised or directed that this accusation should be brought. He received a letter from the secretary to the Council in England, and the inference is he handed it to the persons who acted upon it. As to being a judge, it is not shown that he was present at the Council at the time the report of the committee was dealt with. Something was also said about his being interested. Even if he acted in Ireland when the College decided to withdraw the diploma, and also in England, even on the same evidence this would not show that he was interested. As Mr. Justice Denman has pointed out, the judge who tried a case might also sit and hear the case in the Exchequer Chamber, and afterwards, perhaps, also in the House of Lords. On no one possible ground can the objections taken be maintained. This Court cannot interfere even if they thought the Council had come to the wrong conclusion. I cannot part with this case without saying that, so far from doubting as to whether they were right or wrong, I am perfectly certain they were right. The appeal must be dismissed with costs.

Lord Justice Fry and Lord Justice Lopes concurred.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—The following candidates have passed in the respective subjects:—

Surgery.—A. D. Bensusan and W. T. B. Donelly, King's College Hospital; H. J. Forster, Westminster Hospital; R. T. Gilmour, N. F. Roth, and E. J. Steegmann, St. Mary's Hospital; J. D. Hessey, Middlesex Hospital; F. V. H. Mossman, Owens College; S. A. L. Sodipo, Newcastle-on-Tyne; R. S. Whitford, Charing-cross Hospital; J. Wood, St. Thomas's Hospital.

Medicine, Forensic Medicine, and Midwifery.—P. Goold, Cork; G. B. Hillman, Yorkshire College, Leeds; F. V. H. Mossman, Owens College.

Medicine and Forensic Medicine.—W. D. Akers, St. Mary's Hospital.

Medicine and Midwifery.—V. H. Barr and W. K. Steele, Guy's Hospital; J. Kyffin, London Hospital.

Medicine.—C. A. Davies, Owens College; E. E. Frazer, Guy's Hospital; G. Grace, Bristol.

Forensic Medicine and Midwifery.—C. O'Sullivan, London Hospital; W. A. Ward, Middlesex Hospital.

Midwifery.—J. Dulberg, Owens College; H. F. Ealand, St. Mary's Hospital; A. C. Fenn, St. Bartholomew's Hospital; W. Fowler, Durham University; W. M. Palmer, Charing-cross Hospital; R. A. Smith, Edinburgh.

The diploma of the Society, entitling the candidates to practise Medicine, Surgery, and Midwifery, has been granted to the following gentlemen:—

Messrs. Barr, Bensusan, Donelly, Dulberg, Forster, Goold, Hessey, Mossman, O'Sullivan, Palmer, Steegmann, and Ward.

The results of the examination in Arts qualifying for registration as medical student, held in the Hall of the Society on March 4th and 5th, have just been published. There were 75 candidates, and from the pass list it appears that 2 were placed in the first class and 15 in the second class, and 21 were certified as having passed in some subjects, thus completing for registration. The next examination will be held on June 3rd and 4th, and again on Sept. 2nd and 3rd, 1892.

CHELMSFORD UNION.—At a recent meeting of the guardians it was unanimously resolved to recommend the council to reappoint Dr. Thresh to tabulate the reports of medical officers, at the same salary as before—viz., £100 a year—his term of office having just about expired. The chairman held that the appointment of Dr. Thresh was one of the best things they had ever brought about.

LITERARY INTELLIGENCE.—Messrs. W. Lewis and Son send us a copy of the *édition de luxe* issued in celebration of the centenary of the *Bath Herald*, which occurred on March 5th. The history of the newspaper during the century of its existence is given in the sheet, which is prefaced by a coloured figure of a herald, and which is an excellent specimen of typography.

FEVER EPIDEMIC AT NEW GUINEA.—Reports have been received of a serious loss of life at German New Guinea through an epidemic of fever which had broken out there, the victims including the entire crews of two English vessels. The malady manifested itself chiefly at the port of Frederickshaven. It was thought that the fever was caused by the quantity of rotten coral and undergrowth which was brought to the surface when the land was being cultivated.

YELLOW FEVER.—The captain of the steamer *Colombo*, which arrived at Genoa a few days ago, from Rio de Janeiro, reported that forty-four cases of yellow fever occurred on board during the voyage, fifteen of which had terminated fatally. The vessel was consequently ordered to the quarantine station at the island of Asinara.—The Liverpool steamer *Umbria*, which arrived at Queenstown from Rio and St. Lucia on the 18th inst., had two of the crew fatally attacked with the fever during the voyage.

THE DUFFERIN FUND.—The Viceroy, Lord Lansdowne, presided at the seventh annual meeting of the Countess of Dufferin Fund, held on the 4th ult., at the Town Hall, Calcutta, and, in the absence, from indisposition, of Lady Lansdowne, performed the ceremony of unveiling the portrait of Lady Dufferin. Appropriate tributes were paid by several speakers to her ladyship's beneficent work in India. The annual report was very satisfactory, and was adopted. The number of patients treated during the past year by the Dufferin Institutions amounted to 466,000. Pupils under medical tuition now number 222. As regards finance, the total invested funds altogether reached fourteen and a half lakhs.

LADY ROBERTS' FUND.—But for this important fund not a single lady nurse would be attached to any British soldiers' hospital in India, and the army in India owes a deep debt of gratitude to Lady Roberts, who for the last six years has laboured most earnestly to establish "Homes in the Hills" for lady nurses to recuperate during the hot weather in the plains. Lady Roberts appeals for additional funds to enable the work to be completed when the time comes for her to leave India. The Maharaja of Bettiah has already given a donation of Rs. 5000 towards this end. Lady Roberts is anxious to invest a sufficiently large sum of money to adequately maintain these Homes and Officers' Hospitals when she leaves India. She has already invested Rs. 130,000, but Rs. 250,000 are necessary to enable her to leave the work independent. To complete the work Lady Roberts would like to establish a Home and Officers' Hospital at Naini Tal or Ranikhet.

ROYAL METEOROLOGICAL SOCIETY.—Dr. C. Theodore Williams, the president, delivered an able and interesting address on the "Value of Meteorological Instruments in the Selection of Health Resorts" at a meeting of the Society held last week. He drew attention to thermometers, maximum and minimum, as the foundation stone on which medical climatology rests, and instanced effects of extreme cold, or of heat, on the human organism. He stated that many health resorts owe their reputation almost solely to their shelter from cold winds, and pointed out the advantage of climate in various foreign localities. He referred to the weak points of the South of France climate, but summed up the Riviera winter climate as being, as a whole, clear, bright, and dry, with fog and mist practically unknown. After the delivery of this address the meeting was adjourned in order to allow the Fellows and their friends an opportunity to inspect the exhibition of instruments relating to climatology, which had been arranged at the Institution of Civil Engineers, in Great George-street.

EYE INFIRMARY, BATH.—This institution is nearly the oldest of the medical charities in Bath, and has continued for eighty years to bestow its benefits on the needy citizen and on the adjacent population. More cases were treated during the past than the preceding year. In no previous year has the number of in-patients been exceeded. The out-patients numbered 1733 a slight increase on 1890. The invested funds amounted to £4343 12*s.* 11*d.*

THE METROPOLITAN WATER-SUPPLY.—On Wednesday the first meeting of the Royal Commissioners appointed to consider the question of the water-supply for the metropolis was held at the office of the Board of Trade. Lord Balfour of Burleigh (the chairman) presided, the other Commissioners present being Sir George Barclay Bruce, C.E., Professor James Dewar, F.R.S., Mr. Henry Hill, Mr. James Mansergh, and Dr. William Ogle, with Mr. Francis Gaskell, secretary. The preliminary procedure was discussed, and the Commission adjourned until Wednesday next.

ST. MARY'S HOSPITAL, PADDINGTON.—The report for 1891 is in most respects satisfactory. The number of in-patients and of maternity patients had again increased. The former were 44 and the latter 206, higher than in any previous year. The year's ordinary expenditure shows an excess of £451. The Prince and Princess of Wales, it was stated, would lay the foundation stone of the new wing in October, which will be called, by permission, the "Clarence Wing." For the first time for many years the charity is greatly in debt to the bankers.

DEATH FROM ANTHRAX.—A case of death from anthrax having some interest from a causal point of view recently occurred at Greenwich. At the Guarantee Manure Works a labourer who was employed in lifting bags of manure met with a slight abrasion of his arm. The limb began to swell, and the patient died on the fourth day after the accident, in the Seamen's Hospital. At the inquest evidence of anthrax was given, and the coroner's jury returned a verdict of "Death from anthrax from working in a manure factory."

THE REDDITCH NURSING ASSOCIATION: PROPOSED COTTAGE HOSPITAL.—The annual meeting of this Association was held on the 17th inst. The financial position was satisfactory, and the report was adopted. Mrs. Kenrick, of Birmingham, delivered an interesting address upon the objects and scope of the Association, and Councillor S. Allcock, in moving a vote of thanks to Mrs. Kenrick, urged the desirability of calling a public meeting to consider the question of erecting a cottage hospital for the town. He had already offered £500, if it was decided to build such a hospital, and would give a further sum of £500 towards its endowment. The meeting was also reminded that Mrs. Thomas Bartleet had promised £500 towards the proposed institution.

SANITARY INSPECTORS' ASSOCIATION.—The ninth annual dinner of this Association took place on Saturday at the First Avenue Hotel, Holborn. Dr. B. W. Richardson presided. In proposing the toast of the evening, he stated that there were many preventable diseases which were caused by ignorance and perversity, bad manners, bad social customs, and by negligence. Towards these diseases the Association turned its attention. He congratulated the Association on having obtained a charter of incorporation. They must have a school connected with the Association—a school of health, in which the laws of health and of all that conduced to make their labours useful would be taught.

GENERAL HOSPITAL, BIRMINGHAM.—The report for the past year, so far as the ordinary work of the hospital was concerned, was very satisfactory. The number, both of in- and out-patients, showed an increase on the two preceding years, a result which had only been possible from the accommodation afforded by the Jaffray Branch Hospital in treating some of the cases, and which had proved a valuable auxiliary to the older institution. The musical festival had contributed to the funds £5516. The year's total expenditure was £14,500; no less than £12,000 was disbursed in aiding free cases received into the hospital, without tickets. The plans for the new hospital had been selected, the amount raised for the new building being £88,917.

CITY OF LONDON SCHOOL.—Last week, at a meeting of the Court of Common Council, held at the Guildhall, the Town Clerk laid before the Court notice of a legacy of £300 from the late Dr. H. E. Price of Hove, to found a prize in the City of London School (in which he was formerly educated), under the name of "The Price Prize."

DISEASED MEAT.—A jobbing butcher and a dealer, both of Toftwood, East Dereham, Norfolk, were last week fined at the Guildhall Police court, London, £100, or in default three months' imprisonment, and £20, or a month's imprisonment, respectively, for exposing for sale in the Central Meat Market the carcases of four sheep which were unfit for human food. This was the first case under the new Act, which gives additional powers to the magistrates.

LOUGHBOROUGH GENERAL HOSPITAL AND DISPENSARY.—The annual report for 1891 states that the returns for the year exhibit a great similarity to those of the previous twelve months. Although there was a slight decrease in the number of patients admitted, the average for the two years was practically identical. The expenditure had again exceeded the income, and additional financial support was urgently needed. The St. John Ambulance Association had established itself in the town, and had applied to the committee for assistance in the purchase of their ambulance litter. The litter was now in the hospital, and available in cases of accident.

NORFOLK AND NORWICH HOSPITAL.—The annual report for 1891, just circulated, states that the total amount received during the year (exclusive of legacies and special items) was £7326 8*s.* 8*d*, while the ordinary expenditure (exclusive of special items) was £8771 8*s.*, an excess of £1445. Fees for nurses' services amounted to £287 11*s.* There were 137 more in-patients than the previous year, and also a considerable addition to the number of out-patients. The building of the convalescent home, so munificently offered by Mr. R. E. Fletcher as a gift to the hospital, and which the president, the Earl of Leicester, has generously offered to endow, is making satisfactory progress, and will, it is hoped, be ready for occupation during the present year.

CHILDREN'S HOSPITAL, SHEFFIELD.—The full average extent of work done in this institution during the past year was well maintained. The expenditure had exceeded the income by a comparatively small amount. But the capital account was increased by £324. During the year twenty-six cots had been supported by endowments, or cot subscriptions. There was accommodation for thirty-two cots in all. The board had been considering a scheme for the establishment of a branch hospital at the east end of the town. A Sheffield gentleman, who did not wish his name to be mentioned, had intimated his intention to settle a large amount upon certain trusts for the purpose of establishing such a branch. The property would produce £1000 per annum. The necessary legal transfer to the trustees appointed was completed in October last, but the gift cannot by law take legal effect until twelve months after that date.

GENERAL PRACTITIONERS' ALLIANCE.—At a meeting of the Council of this Society, held on Monday last, the subject of the proposed Gresham University was discussed, and the following resolution was unanimously carried and the President instructed to forward a copy of the same to the Lord President of the Privy Council:—"That the Council of the General Practitioners' Alliance have heard with pleasure that Her Majesty's Government have determined to refer the Draft Charter of the Gresham University to a Royal Commission, and would respectfully urge upon the Lord President of the Privy Council the importance of nominating one or more medical men in general practice to serve on the said Commission, in order that the 22,000 general practitioners in the United Kingdom whose interests will be vitally affected by the proposed measure may be directly represented." The proposed Royal Charter to the Royal British Nurses' Association was laid before the Council, and after due consideration it was resolved to hold a general meeting of members of the Alliance on April 12th next, for the purpose of discussing what action, if any, shall be taken by the Alliance in the matter.

ST. JOHN AMBULANCE ASSOCIATION.—At a special military class held at the Portsmouth centre of the St. John Ambulance Association, the lecturer being Surgeon-Captain C. R. Kilkelly, Medical Staff, and the Examiner Fleet Surgeon H. C. Woods, R.N., of the Royal Yacht, fifty-three candidates came up for examination and fifty-one were awarded certificates.

CHESTERFIELD AND NORTH DERBYSHIRE HOSPITAL. This charity has again made satisfactory progress during the past year; 301 patients were admitted, and 1776 out-patients were attended at the dispensary. The year's expenditure was slightly less than the previous year, and the receipts £128 3*s.* 10*d.* more. The erection of the new buildings, to form the new wing, had been much delayed by unexpected difficulties in laying the foundations, but the buildings are now being actively pressed forward. The Duke of Devonshire has been elected president in succession to his father, the late Duke.

INSANITARY PEABODY DWELLINGS.—Last week the Peabody Trustees were summoned at the Westminster Police Court, at the instance of the Vestry of St. Margaret and St. John, Westminster, for failing to comply with a requisition to remove existing inlets to a dust-shoot. The dust-shoot ran through the building from top to basement. From these inlets, when used, objectionable particles and effluvia were blown about the building. A letter was read from the trustees offering to make substantial alterations to meet the objection. The magistrate said the difficulty was obviously due to an inherent defect in building, and adjourned the case, pending a satisfactory arrangement being made.

BEQUESTS AND DONATIONS TO HOSPITALS.—The late Mr. Charles Ravenhill, of Bushey House, Streatham Hill, bequeathed £1000 each to the London Hospital, St. Bartholomew's Hospital, Brompton Hospital for Consumption, and the Samaritan Free Hospital.—Mr. Samuel F. Harrison, late of Wakefield, bequeathed £500 to the Convalescent Home at Lupset. The residue of the deceased's estate is for the benefit of the Clayton Hospital, Wakefield.—"A Lady" has sent a donation of 100 guineas to the British Home for Incurables (Offices, Cheapside, London).—Mrs. Katharine Bright, late of Stocks House, Tring, bequeathed £1000 to the West Herts Infirmary.—The late Mr. Joseph Johnstone, of Carlisle-place, Manningham, bequeathed (free of legacy duty) £500 to the Bradford Infirmary, and £250 each to the Eye and Ear Hospital and the Bradford Children's Hospital.—Mrs. Emma M. Evans, late of Lyndhurst-gardens, Hampstead, bequeathed £200 to the Royal Hospital for Incurables.—The late Mr. James Graham, of Holland Park, Kensington, bequeathed (free of legacy duty) £3000 to the London Hospital, Whitechapel-road, £2000 each to the West London Hospital, Hammersmith-road, St. Mary's Hospital, Paddington, and the Glasgow Royal Infirmary, and £1000 to the National Hospital for the Paralysed and Epileptic, Bloomsbury. The Goldsmiths' Livery Company has made a grant of £1000 to the London Hospital.

MEDICAL NOTES IN PARLIAMENT.

Sanitary Order at Gibraltar.

IN the House of Commons, on Friday, the 18th inst., in answer to Mr. Causton, Baron H. de Worms said: By the Sanitary Order Amendment Order (Gibraltar), 1891, the number of members of the Board of Sanitary Commissioners of Gibraltar representing the rate-payers and inhabitants has been diminished from eight to four. The order was put in force without notice; but the reasons which rendered the measure necessary have since been published in Gibraltar, and it is not proposed to withdraw the order.

The Gresham University.

On Monday Lord A. Hill, Comptroller of the Household, brought up the answer of Her Majesty the Queen to the Address of the House with respect to the proposed Charter. Her Majesty intimated that she would, for the present, withhold her consent to the scheme, in accordance with the desire of the House.

The Sanitary Condition of Santos.

Mr. J. W. Lowther, in reply to Mr. Duff, said that instructions were sent to Her Majesty's Minister at Rio in October and in February to bring this matter to the attention of the Brazilian Government, which was accordingly done. Mr. Wyndham was further instructed on the 9th inst. to press the matter upon their attention. The insanitary condition of the port of Santos has been made known to the shipping community by the Board of Trade, by notices in the *Board of Trade Journal*, by means of a notice posted in all the shipping offices, and in other ways.

Insanitary Barracks.

Mr. E. Stanhope informed the House that the amount now being expended on barracks, both out of loan funds and out of annual estimates, though it would not suffice to rebuild all the barracks, would practically remove the evils specially brought to his notice.

Fatal Vaccinations.

Mr. Ritchie, answering Mr. Channing, said his attention had been called to an inquest in the case of the child said to have died from the result of vaccination. The Local Government Board had informed the Royal Commission of the certificate which had been received. He learned that the Commissioners had no knowledge of the case until after the inquest had been held, and it was impossible to have a medical examination of the body. They were, however, otherwise inquiring into the case.

The Case of Surgeon-Major Briggs.

In the House of Commons, on Tuesday, the 22nd inst., Dr. Farquharson asked the Secretary of State for War whether he had further considered the case of Surgeon-Major Briggs, of the Army Medical Staff, with the view of his being reinstated in the position which he would now occupy in the service if he had not retired.—Mr. E. Stanhope: Yes, sir; I have further considered the case, and I am of opinion that Surgeon-Major Briggs should not suffer any loss as regards position or promotion in consequence of an act which any gentleman was bound to perform, and which he performed under pressure which no one could have resisted. Dr. Briggs will therefore be restored to the seniority he held before retirement.

Protection against Accidents at the London Docks.

In answer to Mr. Johnston, Sir M. Hicks-Beach said: I directed Captain Pitman (my chief superintendent at Poplar) to place himself in communication with the dock authorities, and I am happy to say that they willingly agreed to erect stanchions and chains at a number of places agreed upon. Captain Pitman has now reported to me that the directors have made every effort to provide for the safety of the public by adopting all reasonable precautions. I understand that the London and India Docks Joint Committee alone have ordered no less than seven miles and a half of chains and standards.

The Treatment of City Refuse.

On Thursday, the 24th inst., in the House of Commons, Mr. Ritchie, answering a question by Mr. Pickersgill, said that the Local Government Board had no information as to the intention of the Strand District Board to erect a destructor on the Surrey side of the river, near Waterloo Bridge. The matter was not one in which the Local Government Board had any jurisdiction. He might say that a clause was inserted in the Public Health Act of last year to meet the case of a local authority which used premises for the treatment or disposal of refuse in such a way as to be a nuisance or a danger, or injurious to health.

METROPOLITAN ASYLUMS BOARD.

Return of Patients remaining in the several Fever Hospitals of the Board at Midnight on March 22nd, 1892.

munity by the Board of Trade, by notices in the *Board of Trade* by means of a notice posted in all the shipping offices, and in other ways.

Insanitary Barracks.

Mr. E. Stanhope informed the House that the answers to questions on barracks, both out of loan funds and out of annual votes, though it would not suffice to rebuild all the barracks, would suffice to remove the evils specially brought to his notice.

Fatal Vaccination.

Mr. Ritchie, answering Mr. Channing, said his attention had been called to an inquest in the case of the child said to have died as the result of vaccination. The Local Government Board had not received the Royal Commission of the certificate which had been given, but had learned that the Commissioners had no knowledge of the case before or after the inquest had been held, and it was impossible to have an examination of the body. They were, however, about to make inquiries into the case.

The Case of Surgeon-Major Briggs.

In the House of Commons, on Tuesday, the 22nd inst., Mr. Johnston asked the Secretary of State for War whether he could say if he had entered the case of surgeon-Major Briggs, of the Army Medical Staff, with the view of his being reinstated in the position which he would occupy in the service if he had not retired.—Mr. E. Stanhope replied that I have further considered the case, and I am of opinion that surgeon-Major Briggs should not suffer any loss in regard to his promotion in consequence of an act which any gentleman might refuse to perform, and which he performed under pressure which he could hardly have resisted. Dr. Briggs will therefore be restored to the seniority he held before retirement.

Protection against Accidents at the London Docks.

In answer to Mr. Johnston, Sir M. Hicks-Beach said Her Majesty's Captain Pitman (my chief superintendent at Poplar) has been in communication with the dock authorities, and I am glad to say they willingly agreed to erect stanchions and chains at those places agreed upon. Captain Pitman has now reported that the dock authorities have made every effort to provide for the safety of the public, and have taken all reasonable precautions. I understand that by the end of June all reasonable precautions. I understand that by the end of June all reasonable precautions. I understand that by the end of June

Medical Diary for the ensuing Week.

Monday, March 28.

ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M., and on Tuesday, Wednesday, Friday, and Saturday at the same hour.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations daily at 10 A.M.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.

CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M.; Thursday, 2.30.

HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.

METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.

ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.

CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M., and each day in the week at the same hour.

UNIVERSITY COLLEGE HOSPITAL.—Ear and Throat Department, 9 A.M.; Thursday, 9 A.M.

MEDICAL SOCIETY OF LONDON.—8 30 P.M. Dr. Amand Routh: Rapid Dilatation of the Uterus for Diagnosis and Treatment in cases of Uterine Hæmorrhage (with cases).

Tuesday, March 29.

KING'S COLLEGE HOSPITAL.—Operations, 2 P.M.; Fridays and Saturdays at the same hour.

GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at same hour. Ophthalmic Operations on Monday at 1.30 and Thursday at 2 P.M.

ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.

ST. MARK'S HOSPITAL.—Operations, 2 P.M.

CANCER HOSPITAL, BROMPTON.—Operations, 2 P.M.; Saturday, 2 P.M.

WESTMINSTER HOSPITAL.—Operations, 2 P.M.

WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Consultations, Monday, 2.30 P.M. Skin Department, Monday and Thursday, 9.30 A.M. Throat Department, Tuesdays and Fridays, 1.30 P.M. Electro-therapeutics, same day, 2 P.M.

ROYAL INSTITUTION.—3 P.M. Professor V. Horsley: The Brain.

THE QUEEN'S COLLEGE, BIRMINGHAM.—4 P.M. Dr. Arthur Foxwell: The Condition and Treatment of the Vascular System in Chlorosis and other Debilitated States. (Ingleby Lecture)

ROYAL COLLEGE OF PHYSICIANS (Examination Hall, Victoria Embankment).—5 P.M. Dr. Sidney Martin: Chemical Pathology of Diphtheria compared with that of Anthrax, Infective Endocarditis, and Tetanus. (Third Goulstonian Lecture.)

Wednesday, March 30.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.

MIDDLESEX HOSPITAL.—Operations, 1.30 P.M.; Saturdays, 2 P.M. Obstetrical Operations, Thursdays, 2 P.M.

CHARING-CROSS HOSTITAL.—Operations, 3 P.M., and on Thursday and Friday at the same hour.

ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour.

LONDON HOSPITAL.—Operations, 2 P.M.; Thursday & Saturday, same hour.

ST. PETER'S HOSPITAL, COVENT-GARDEN.—Operations, 2 P.M.

SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.

GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 1.30 P.M.; Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.

ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.

CHILDREN'S HOSPITAL, GREAT ORMOND-STREET.—Operations, 9.30 A.M. Surgical Visits on Wednesday and Saturday at 9.15 A.M.

Thursday, March 31.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M. Surgical Consultations, Wednesday, 1 30 P.M. Ophthalmic Operations, Friday, 1.30 P.M.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Ear and Throat Department, 9 A.M.

ROYAL INSTITUTION.—3 P.M. Dr. B. A. Whitelegge: Epidemic Waves.

CHELSEA HOSPITAL FOR WOMEN.—5 P.M. Dr. F. F. Schacht: Minor Manipulations of Gynæcology.

ROYAL COLLEGE OF PHYSICIANS (Examination Hall, Victoria Embankment).—5 P.M. Dr. Pye-Smith: Certain Points in the Etiology of Disease. (First Lumleian Lecture.)

Friday, April 1.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

WEST KENT MEDICO-CHIRURGICAL SOCIETY (Royal Kent Dispensary, Greenwich).—8 P.M. Discussion on Influenza, to be opened by Dr. Geo. Newton Pitt.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—8 P.M. Pathological Specimens by Dr. Ball and Mr. Dunn.—Dr. W. P. Herringham: Lumbago and Sciatica.—Dr. Symons Eccles: Sciatica.

ROYAL INSTITUTION.—9 P.M. Prof. Oliver Lodge: The Motion of the Ether near the Earth.

Saturday, April 2.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; and Skin Department, 9.15 A.M.

ROYAL INSTITUTION.—3 P.M. Prof. J. F. Bridge: Dramatic Music.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

We cannot undertake to return MSS. not used.

CHAPPED HANDS.

Mr. Edgar Duke (St. Leonards) recommends for this affection the application of equal parts of glycerine, sulphurous acid, and rose-water several times a day. It will be found, he says, that the "chaps" will soon heal; and, as an additional aid, "Penton" might, if necessary, advise his patient to wear white kid gloves at night after using the liniment.

Dr. Thursfield recommends one part of the glycerole of subacetate of lead with seven of glycerine, to be used with indiarubber gloves, so as to keep up free moisture of the skin.

F. R. C. (Dublin) writes: "If 'Penton' has not yet used it, he might try 'luna-creolin.' Its name indicates its composition. I have had it from Messrs. Burroughs, Wellcome, and Co. It may be used freely, especially in the evening, and chamois-leather gloves should be worn at night."

Cyclops suggests that "Penton" should try the following:—Liquor plumbi diacetatis, ʒi.; creta præparata et ol. olivæ, q.s. of each to make an ounce of the consistence of an ointment. The hands to be well smeared with this each night, and a pair of soft gloves worn. If tried, will "Penton" communicate results?

A correspondent writes that "Penton" might find holding the chapped hands over the fumes of sulphur twice daily of use. Our correspondent has known it to answer well in obstinate cases.

A QUESTION OF ETHICS.

To the Editors of THE LANCET.

SIRS,—On opening my daily paper on Friday, March 18th, I noticed nearly a column was occupied with an extract from one of your medical contemporaries concerning a person of unhappy notoriety. I was not surprised at this; but I was astonished to see details given on the authority of the medical attendants in the case. That there should be no room for mistake, the names and addresses of these medical men are published in full. Now, this constitutes a breach of confidence, and when I was in active practice would have been considered professional conduct the reverse of graceful. Has the code of honour been revised?

I am, Sirs, yours obediently,

March 21st, 1892. ONE OF THE OLDEN TIME.

REFUSAL TO PAY NOTIFICATION FEES.

Dr. J. L. Kerr.—Under the Notification Act we apprehend that the local authority is bound to pay the fee for notifying the specified diseases in every case, and could be compelled to do so at law. The medical officer of health has no authority as a taxing master.

Digitized by Google

THE DUBLIN CIVIL SERVICE MEDICAL AID ASSOCIATION.

Mr. J. J. Murphy has kindly forwarded to us a letter correcting our allusion to the terms of membership of the Association, and showing that the married members' subscriptions are at the rate of £1 a year and those of unmarried members at the rate of 10*s*. Our mistake was in regarding quarterly subscriptions as annual ones. We still think the terms low; £1 a year for attendance on a member of the civil service, on his wife (barring midwifery) and children, and any other relatives permanently residing in such member's house, together with their domestic servants, is, or strikes us as, very inadequate remuneration. We have no doubt the civil servants in Dublin get good medical treatment, but we deny that the pay for it is "reasonable." We are much obliged to Mr. Murphy for his note, and to the secretary for a copy of the rules.

Scapula.—The services are so peculiar and exceptional that we have a difficulty in appraising them. Our correspondent will do that best himself. His actual charge is not too much, but it looks high. And the service to his patient is withal so delicate that he would do well, while maintaining its reasonableness, to be ready to argue the sum. Fees for such duties should always be a matter of understanding beforehand. For ourselves, we should be very unwilling to undertake such duties until the law shall enable them to be discharged within the bounds of the United Kingdom.

E.L.—We have no reason to suppose that injury would result from the use of such a writing implement.

PERFECT COMBUSTION AND SMOKE PREVENTION.

To the Editors of THE LANCET.

SIRS,—I have been much interested in reading the article in THE LANCET on the subject of perfect combustion and smoke prevention. If an Act could be passed under which all new stoves would be required to pass a certain standard of smoke combustion, it would soon lead to further inventions and improvements, and the old stoves now in use in London would be to a great extent replaced, more especially when the saving in cost is brought home to the minds of the householders. A good combustion stove would be a literal godsend to scores of large buildings where the flues draw badly, and can only be imperfectly swept from the top. It would be difficult to enumerate all the advantages likely to arise from even a partial consumption of smoke. It is highly probable that we suffer from a far more dangerous evil than that of smoke brought down by the fog—viz., the foul air proceeding from the innumerable ventilation pipes from house drainage; and in connexion with this it has been suggested that the climax in the late scourge of influenza was reached at the time of the late fogs, and that the horrible atmosphere we then breathed was tainted by the gases proceeding from the ventilation pipes. These ventilation pipes are, of course, essential under the present system; but the time, I think, will, and must, come when the entire system of sewers will be ventilated by tall shafts and furnaces in central positions, through which the foul air will be drawn, and its deadly properties, including microbes &c., be consumed.

I am, Sirs, yours faithfully,

Bedford street, W.C., March 8th, 1892. JOHN T. WOODARD.

A GRIEVANCE OF TITLE.

New L.S.A.—We are constantly receiving letters from the new class of L.S.A. complaining of the inadequacy of the title Apothecary, and demanding one that expresses the fact of their full qualification in Medicine, Surgery, and Midwifery. We entirely sympathise with this feeling. The nature of the education and examination for the L.S.A. has been altered and enlarged by the Act of 1886, and there should be a corresponding alteration and enlargement of title. But it will never be procured unless the Society and its Licentiates bestir themselves. Let a committee be organised to press the grievance till it is removed.

Mr. Woodcock.—The production of the Clausen stove has been delayed by the somewhat sudden death of the inventor. It is to be hoped that so useful and economical an appliance will before long be generally introduced.

Mr. T. Johnston.—We think it desirable to wait for the reply to our correspondent's complaint, which seems a very reasonable one.

A QUERY.

To the Editors of THE LANCET.

SIRS,—Can any of your readers inform me whether there is any institution where a little boy three years old, who has lost both arms, can be educated, and taught how to use his feet?

I am, Sirs, yours faithfully,

March 17th, 1892. HOUSE SURGEON.

THE OPENING OF PAROCHIAL HOSPITALS TO STUDENTS.

DR. CAMPBELL BLACK, in the *Glasgow Herald*, advocates the opening of parochial hospitals to students, and the much wider distribution in the profession of hospital appointments.

PROFESSIONAL FEES AMONG THE ISRAELITES.

ON this subject there is a curious document, of which the Hebrew original is lost. It is the "Ecclesiasticus" of the Son of Sirach, Jesus by name, a book not accepted by Jews or Protestants as part of the Bible, but included in the so-called "Apocrypha." Another Jesus, grandson of the above-named, has left a Greek version of it, and St. Jerome, who says he saw it in its original Hebrew, has translated it into Latin. The Talmud contains some fragments of that original. The opening words are in the Vulgate as follows: "Honora medicum, propter necessitatem; etenim illum creavit altissimus." (Honour the physician, because thou hast need of him; for he was created by the Most High.) In this passage "honorare," it has been remarked, means not only to "respect," but to "give *honoraria*" (fees). In this sense the Greek of the Septuagint corresponds with the Latin. The passage proceeds: "A Deo est enim omnis medela et a rege accipiet donationem." (From God indeed comes all healing, and the king will crown it with presents.) Again: "Disciplina medici exaltabit caput illius et in conspectu magnatorum collaudabitur." (The culture of the physician will exalt his head, and in the presence of princes he will be praised.) Yet again: "Altissimus creavit de terrâ medicamenta, et vir prudens non abhorrebit illa." (The Most High has made medicines to spring from the earth, and the wise man will not abhor them.) After a eulogy of the virtues of these medicines, especially as prepared by the apothecary, the passage resumes: "Etenim Dominus creavit illum [medicum] et non discidat a te, quia opera ejus sunt necessaria." (For the Lord has created him [the physician], and let him not abandon thee, for his works are necessary to thee.) The English version from the Greek of the Septuagint is substantially the same as the above rendering from the Vulgate. See "Archéologie Médicale de l'Égypte et de la Judée," par le Dr. Beugnies-Corbeau (Liége, 1891).

F.R.C.S. (Belfast) writes: "'Baffled' will find by reference to THE LANCET, Dec. 6th, 1884, p. 996, that dysmenorrhœa and several other neuroses are at once relieved by applying a blister 3 × 2 in. for six hours over the region of the fourth and fifth dorsal vertebræ—in this case a week before the monthly period."

L.R.C.P.Lond., M.R.C.S.—Application should be made at the Office of the Crown Agents for the Colonies, Downing-street, London, S.W.

Scrutator.—No; there is no evidence to justify the conclusion mentioned by our correspondent.

Etiquette.—The subject is treated in another column of our present issue.

WOOD PAVEMENT.

To the Editors of THE LANCET.

SIRS,—Adverting to the annotation in your issue of the 19th inst. respecting the cleansing of wood pavements so commonly used in many large towns throughout England, I take the liberty of directing your attention to "Tuson's Fluid," by the use of which the evils referred to in your article may be entirely prevented. This fluid, as you are aware, consists of a solution of chloride of zinc saturated with sulphurous acid gas, and acts not only by deodorising malodours arising from the droppings of animals, but also as a powerful germicide, in addition to which it is useful, when properly diluted and used in the ordinary watering cart, in allaying dust. In the City of London and in some of the large sanitary districts of the metropolis a 3-per-cent. solution of Tuson's fluid, used in this manner, has been found of signal service after the roadways have been swept by the scavengers at night (so as to prevent unnecessary interference with the traffic). During the recent epidemic of influenza it was employed extensively in large buildings, notably Gresham College, justice rooms, and other places.

I am, Sirs, yours faithfully,

March 23rd, 1892. AMBULATOR.

SALE OF LIQUOR TO CHILDREN.

A PUBLIC meeting has been held in Liverpool to form a league to prohibit the sale of drink to children. Mr. Thomas Pegrim presided. We heartily wish success to such an effort. It is monstrous that children should be allowed to enter public-houses. This is an evil which the police might greatly lessen if they were required to report on it in every case.

Erlangensis.—The question is one we cannot decide, and should be referred to a medical bookseller.

Coroner will see that the matter is referred to in our correspondence columns.

TREATMENT OF CRACKED LIPS.

To the Editors of THE LANCET.

SIRS,—Can any of the readers of THE LANCET oblige me with hints as to the treatment of cracked lower lip in a boy aged fourteen years, who is in good health in every other respect?

I am, Sirs, yours faithfully,

March 22nd, 1892. MEDICUS.

Goulstonian Lectures

ON THE

CHEMICAL PATHOLOGY OF DIPHTHERIA COMPARED WITH THAT OF ANTHRAX, INFECTIVE ENDOCARDITIS, AND TETANUS.

By SIDNEY MARTIN, M.D., F.R.C.P.,

ASSISTANT PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL AND TO THE HOSPITAL FOR CONSUMPTION, BROMPTON; LATE PATHOLOGIST TO THE MIDDLESEX HOSPITAL.

LECTURE II.

Examination of the nervous system.—All parts of the nervous system were examined. The motor nerves were cut out with a piece of muscle attached, so as to admit of the examination of the intra-muscular branches. The only method which is of value in the study of peripheral nerve degeneration is staining the fresh nerve with osmic acid, so that the white substance of Schwann is stained black, and counterstaining with carmine to bring out the nuclei and axis cylinder. In all the animals the same changes were found in the nerves, and the following description of the pathological condition refers to specimens taken from the animals as illustrating the points to be referred to.

Motor nerves.—After the motor nerve with the piece of muscle attached has been stained in osmic acid, it is separated from the muscle with its intra-muscular branches as far as possible. When a small intra-muscular nerve is mounted whole as a specimen it is seen that the nerve is stained black with osmic acid, except at certain points just before it divides into branches. At these points the nerve is attenuated and degenerated. This serves as a type of the degeneration in the nerves, and its microscopic characters showed that all the parts near the origin of the nerve were quite normal. When the nerve is teased with needles from the normal part to the end of the small branches, it is found that at the upper part the fibres are normal; a little lower down they show a breaking up of the white substance of Schwann, which is becoming thin and is but little stained by the osmic acid, while lower down still the white substance disappears altogether. This is at the portion of the nerve unstained by osmic acid. Beyond this the white substance again appears, but it is very pale, granular, and broken up; lower down still it regains its dark colour. The primitive sheath of the nerve is intact throughout; the axis cylinder may be intact down to the spot at which the white substance completely disappears, and even through this part, so that here the majority of nerve fibres consist only of axis cylinder and the primitive sheath. Below the point at which the white substance has disappeared the axis cylinder is in many instances broken. When the axis cylinder is ruptured the upper end is often seen bulbous, and both peripheral and central parts become wavy. After such rupture of the axis cylinder the nerve fibre undergoes below the rupture the Wallerian degeneration, the features of which are well known, and consist of a breaking up of the white substance along the whole course of the fibre, the axis cylinder also degenerating, portions becoming isolated. Many of the fibres, however, below the segment of degeneration do not undergo degeneration, showing that the axis cylinder is intact. Another branch of the nerve may show a less degree of change, and a third branch may show the earliest stage of the degeneration, of which I shall speak later. It will be seen that the degeneration affects primarily a portion of the nerve. It is a degeneration of the nerve fibre itself. There is no interstitial change, no increase of nuclei, which, in fact, themselves undergo an atrophy in the most advanced part. The part of the nerve fibre primarily affected is the white substance of Schwann, which breaks up and finally disappears. The axis cylinder itself may be unruptured when the white substance has completely disappeared; but it often becomes ruptured lower down the nerve fibre, which then undergoes below the rupture the Wallerian degeneration. The different branches of the motor nerve itself are affected to a varying degree, so that in an individual motor nerve there are many fibres which can still innervate the muscle, owing to the integrity of the axis cylinder. This is one reason why the condition observed during life is a paresis, and not a paralysis. In the nerve we have just been considering the degeneration is seen right across the nerve; but in many nerves the change affects only a few fibres lying side by side, or a single bunch of fibres. This is well seen in many specimens of the phrenic nerve from these animals, and also in the anterior roots of the spinal nerves. The earliest stage of this change in the motor nerve is the breaking up of the white substance in a portion of the nerve, while the axis cylinder may still be unaffected; so that, in this early degeneration, it is not uncommon to find that the nerve above and below the affected portion is quite normal. In some instances, however, this early segmentation of the white substance is associated with rupture of the axis cylinder. The attenuation of the white substance which follows its breaking up may occur in the middle of an internode; it may also occur near the node. The more minute changes in the nerve fibres may be observed in many specimens, in which the white substance is seen granular and becoming attenuated from without inwards, while the axis cylinder can be traced as a straight line in the centre of the nerve fibre. In the nerve fibres lying by the side of such a fibre the white substance shows similar appearances, but the axis cylinder is wavy and may become attenuated.

Multiple interrupted degeneration.—There may be more than one portion of the nerve affected by the degeneration, and when this is so the whole nerve is liable to degenerate towards the periphery, and presents to the naked eye a nodular or interrupted appearance, the nodules being between the portions of the nerve which were first degenerated. In such a nerve in which there are from three to five degenerated segments, the later stages of the degeneration may be seen. In most of the fibres only a primitive sheath and nuclei are to be seen with a few badly stained droplets of white substance, and here and there a trace of the degenerated axis cylinder. Such is the change in the motor nerves. The muscles to which the nerves go are also degenerated, this degeneration being proportional to the degree of nerve change. If the nerve is completely degenerated, the muscle fibres show an advanced fatty degeneration in minute granules, staining black with osmic acid. When the degeneration is less, fatty fibres are found mixed with normal ones, or only parts of fibres may be fatty, and when the nerve change is only slight there may be only longitudinal striation of a few fibres, or, indeed, the muscle may appear normal. The very partial fatty degeneration of the muscle is evidently dependent on the fact that the axis cylinders are in many instances intact. The heart muscle is, however, in all these cases in an advanced degree of fatty degeneration. On what this cardiac degeneration depends it is difficult to say. I have not found any degeneration in the vagus nerve. It possibly depends on the altered condition of the blood which has been already described, or, indeed, the diphtheria albumoses may have a special action on the heart.

Sensory nerves.—The sensory nerves are affected in a manner similar to the motor. Sensory nerves in any part of the body may show one or more degenerated portions. In one case the long saphenous nerve near the knee showed five degenerated portions, which give the nerve a nodular appearance.

Sympathetic nerves.—In one instance the trunk of the cervical sympathetic just above the third ganglion showed a degeneration which went right across the nerve and was of the same character as in the motor nerve, except that here, of course, the axis cylinders are more profoundly affected than in the medullated nerve fibres. On each side of the degenerated portion there was an increase in the number of nuclei. Above it the nerve was normal, below many fibres were degenerated. From the facts just recorded it is evident that the paresis observed is due to degeneration of the nerves themselves, and that any of the nerve fibres of the body, whether medullated or non-medullated, may be affected. The spinal ganglia, spinal cord, medulla, and brain were in all cases found normal. The distribution of the nerve change may be seen by a description of what was found in one of the animals. In one leg all the motor nerves investigated showed a greater or less degree of degeneration. The change was most marked in the nerves of the sartorius, the vastus, semi-tendinosus, le...

marked in those to the semi-membranosus, biceps, gastrocnemius, and soleus. In the long saphenous nerve, a sensory one, there was well-marked degeneration. Transverse sections of the sciatic at the upper part showed that the nerve trunk was normal. At the lower part the whole nerve was teased and was found normal. The fact is clear, therefore, that the degeneration affects the terminals of the motor branches, and not the main trunk. There may be one or two degenerating fibres in the sciatic nerve if the spinal nerve roots supplying it are affected, but in this particular instance the sciatic nerve was normal. Passing to the trunk, still in the same animal, one of the large branches to the psoas muscle showed well-marked degeneration. A cutaneous nerve of the abdomen was found normal, and of three pairs of spinal roots examined, one in the cervical, one in the dorsal, and one in the lumbar region, degeneration was found in only one anterior root in the dorsal region, the remainder of the anterior roots and all the posterior roots being normal; the spinal ganglia were also normal. In the arm nerves the branches of the musculo-spiral to the triceps and to the flexor muscles of the forearm showed well-marked degeneration, while the branches of the brachial plexus to the pectoralis and to the biceps showed an early stage of the degeneration. The musculo-spiral examined just above the origin of the branches to the triceps was normal. The phrenic showed degeneration; the recurrent laryngeal also, but the trunk of the vagus in the neck was normal. The cervical sympathetic showed well-marked degeneration at the lower part; while above, it was normal; and branches of the third nerve to the eye muscles showed well-marked degeneration. From this it is seen how widespread is the change in the peripheral nerves, whether cerebral, spinal, or visceral, as the result of the injection into the circulation of so small a dose as 0·1565 gramme (in two doses) in a rabbit weighing 1565 grammes, which is a dose of about two grains and a half in a rabbit weighing 3½ lb.

Microscopical examination of the nerves after single doses of the albumoses.—It has already been stated that in rabbits which have a single large dose, although they show fever for a few days, there is no paralysis. One animal which received 0·084 gramme per kilogramme subcutaneously was killed in 115 days; and another, which had a dose of 0·117 gramme per kilogramme intravenously, was killed in ninety-four days. When killed both were fat and well nourished. On microscopical examination, it was found that in both animals the phrenic nerves and the small branches of the motor nerves showed well-marked degeneration with rupture of a few axis cylinders, but no well-marked Wallerian degeneration below the degenerated segment. The heart was fattily degenerated. A single dose of the poison, therefore, although its effects had apparently passed off during life, was found after death to have left a definite nerve lesion which had not been repaired. These two experiments, with the others previously mentioned, show most clearly that the diphtheria albumoses, although fever producers, are nerve poisons, selecting the peripheral nerves for its action, just as strychnine selects the motor cells of the cord for its action. I take it that with these single doses the injury to the nerves had been effected, and the degeneration was not progressing when the animals were killed; whereas the successive introduction of small doses into the circulation keeps up the action on the nerves, so that a visible affection of motility results. In a case of diphtheria that proved fatal I found in the small branches of the phrenic portions of the nerve degenerated, thus demonstrating what has been known before, that nerve degeneration may be present during the acute disease.

Relation of the nerve degeneration to the changes in the nervous system in diphtheritic palsy in man.—Since Dejérine's[1] work on the subject it has been recognised that the paralysis following diphtheria is due to a parenchymatous degeneration in the peripheral nerves. But both before this period (1878) and after, many observers have described changes in the cells of the anterior cornua of the spinal cord, and some have gone so far as to ascribe all the symptoms to a mild polio-myelitis. The symptoms, however, are not those of an affection of the anterior cornua of the spinal cord, as there is an absence of any special wasting of the affected muscles and of the reaction of degeneration. The changes that have been described as occurring in the cells of the anterior horns (such as fatty degeneration, vacuolation, pigmentation, atrophy) are probably only phenomena added to the change in the peripheral nerves, and the poison which produces a change in these nerves and fatty degeneration of the heart may after a time affect the nutrition of the nerve centres, causing first fatty degeneration, then atrophy of the cells. The great argument in favour of the change being essentially peripheral is the fact that sensation is affected and no changes have been described in the posterior cornua of the cords or in the sensory ganglia. In my experiments the cord and spinal ganglia were quite normal. The nature of the nerve change observed in the experiments with the diphtheria albumoses was first described by Gombault[2] as the result of chronic poisoning by lead in guinea-pigs. He called the change "*névrite segmentaire péri-axile*," or a neuritis affecting the nerve fibre around the axis cylinder. His animals showed no paralysis, and he left them alive six months or longer; so that, as his figures show, he had the appearances both of degeneration and of restoration in the nerve fibres. It is clear, from the changes observed in the nerves following the injection of diphtheria albumoses, that the condition is one of simple degeneration, affecting first of all the white substance of Schwann, which breaks up and finally disappears; then the axis cylinder, which is attenuated, and finally ruptured in some fibres, so that below this ruptured axis cylinder the fibre undergoes the Wallerian degeneration and the muscle fibre becomes fatty. Many of the fibres which show a degenerated white substance of Schwann do not show a ruptured axis; and this, combined with the fact that the small branches of the motor nerve are affected to a varying degree, and that the motor nerves of the body are not all in the same degree of degeneration at the same period, demonstrates why diphtheritic palsy is not a complete, but only a partial paralysis. In the degenerated nerves in human diphtheritic palsy an increase of nuclei of the nerve fibres has been described, and also nodular swellings on the nerves formed by cellular elements.[3] These changes probably only indicate an attempt at repair of the nerve; they are not met with in the cases of simple nerve degeneration seen in the artificially produced diphtheritic palsy. Meyer, who very thoroughly examined a case of diphtheritic palsy in man, gives figures which show quite clearly that the change in the peripheral nerves is of the same nature as that which I have described as occurring in the experimental rabbits. He discusses the nature of this change and refers to Gombault's work, but laid a great deal too much stress on the nodules which occur on the nerves, and which are, as I have shown, the intervals between the degenerated portions.

Action of the organic acid.—When the organic acid found in diphtheria is injected in watery solution into the circulation of rabbits, it produces a moderate degree of fever, which may last one or three days, or may be extremely slight, but nothing further happens to the animal. It may waste a little, but it does not get paralysed, even after a single dose of 0·155 gramme per kilogramme of body weight. Similarly two successive doses equal to 0·095 gramme per kilogramme produce only slight fever on the days of inoculation, but otherwise no effect; no paralysis in twenty-four days. This is a dose of the albumoses sufficient to produce a definite palsy. The animal was killed on the twenty-fourth day. The heart's blood coagulated in a normal manner, and all the internal organs of the body were normal in appearance. On a microscopical examination, however, it was found that the heart showed well-marked fatty degeneration, although not to such a great extent as in the experiments with the diphtheria albumoses. There were a few fatty fibres in the diaphragm, but the parts of the vastus, semi-membranosus, and gastrocnemius examined were quite normal. The phrenic nerve was examined in its upper half and found normal, while the nerves to the semi-membranosus, the vastus, and the gastrocnemius all showed the different stages of the characteristic degeneration already described. The organic acid, therefore, found in the bodies of diphtheria patients is, like the albumoses, a nerve poison, capable of producing the same anatomical change in the nerves. One animal which received a single dose of the organic acid equal to 0·043 gramme per kilogramme of body weight showed well-marked fever, but no paralysis. It was killed in 119 days. It was fat and well nourished,

but showed early fatty degeneration of the heart and diaphragm, and well-marked degeneration in the phrenic nerve. One animal received intravenously a very large dose of the acid on two successive days, the total dose being equal to 0·32 gramme per kilogramme of body weight. No fever, paralysis, or loss of weight ensued; and as the dose given was more than twice the fatal dose of the albumoses, the experiment shows what slightly poisonous properties are possessed by the organic acid. Although, therefore, this organic acid is not nearly so toxic as the albumoses, it has the same action in producing a nerve degeneration. It is not surprising that both the toxic bodies found in a specific disorder should have a similar action; it would, indeed, be more surprising if their physiological effects were different. Having considered the chemistry and physiological action of the toxic bodies present in the bodies of patients dead of diphtheria, we will now discuss the chemical composition of the diphtheritic membrane.

Diphtheritic membrane.—The chemical examination of the diphtheritic membrane presented some difficulty, owing to the small quantity of material obtainable. Membrane removed during life with clean forceps, or a cast of the trachea coughed up after tracheotomy, was placed directly into absolute alcohol, partly to preserve it and partly to kill any micro-organisms present. It was, after a varying time, removed from the alcohol and extracted with sterile 10 per cent. NaCl solution. The membrane formed a gelatinous, mucoid-looking mass in the salt solution, and as this would not filter it was largely diluted and passed through a Chamberland's filter. The filtrate was dialysed till all the salt was removed, concentrated at a low temperature, and precipitated by alcohol. The precipitate, which consisted only of proteid matter, was used for experiment. Without going into the chemical details, the membrane consists of the following proteids. One almost insoluble in saline solutions at the ordinary temperature, which is the fibrin of the membrane; others extracted with saline solution, and consisting of a large quantity of hetero-albumose, which is precipitated by dialysis; and two other albumoses in traces—namely, proto- and deutero albumose. The presence of these bodies shows that the membrane is in process of digestion, hetero-albumose being the first product from the fibrin, proto- and deutero-albumose the final products. Practically, nothing is extracted from the membrane by alcohol; the acid body found in the tissues is present, but only in minute quantities.

Physiological action.—The extract of the membrane which was used for inoculation was whitish yellow, not quite soluble in distilled water, and slightly alkaline. It consisted solely of proteid, a mere trace of hetero-albumose, with traces of proto- and deutero-albumose. Thirty milligrammes were injected into a rabbit weighing 560 grammes, which is equal to a dose of 53 milligrammes per kilogramme of body weight. The first result of the injection was fever, high on the first day, less on the second day, but present also on the fifth day, after which the temperature was normal. Weakness of the hind legs appeared on the first day; on the second day the right hind leg was more paretic than the left; on the third day it was the same, and had lost 30 grammes in weight; on the fourth day the left hind leg was more paretic than the right, and on the fifth day this condition was increased, the leg being held in slight abduction. From this time onward the animal did not jump except on rare occasions, but dragged one leg after the other. The condition remained practically the same till the thirteenth day, when it became ill in a manner similar to that described in the previous animals. The hind legs, although kept extended, were not completely paralysed; flexion was still possible if the legs were mechanically semi-flexed. The fore legs were paretic; the breathing was extremely rapid, and the temperature varied between 96·2° and 96·8°. The animal died during the night. The post-mortem examination showed the blood coagulated in some parts; but when the uncoagulated blood was removed it was found slow in coagulating. As regards the rest of the post-mortem examination, the results were precisely similar to the condition described in the other animals. Micro-organisms were absent from the body, and there was the same degeneration of the peripheral nerves, of the skeletal muscles and of the heart, and the same integrity of the central nervous system as has been already fully described. This result is important, as it shows that in the diphtheritic membrane there exists a poison associated with the proteid and precipitated by alcohol, which produces exactly the same result as the albumoses found in the blood and spleen of diphtheria patients. But it is a poison much more virulent, since a single small dose produces a result which only multiple doses of the albumoses can effect. A single small dose of the albumoses will not produce the progressive paresis observed in this case. For example, a dose of 0·123 gramme of diphtheria albumoses in a rabbit weighing 1050 grammes, which is twice the dose per kilogramme in the animal under consideration, produced only moderate fever, and nothing else. Also, at the same time that this experiment with the extract of diphtheritic membrane was done, an animal was injected with three times the dose of albumoses on three successive occasions—namely, 0·157 gramme per kilogramme in all; and yet the nerve lesions were as well marked in the animal which had the diphtheritic membrane extract as in that which had the albumoses, and death occurred in about the same time—viz., fourteen days. Similarly one of the animals that had nearly twice the dose—namely, 0·83 gramme of albumoses in two successive doses,—although it became paralysed, recovered to a great extent, and lived over ten weeks. The toxic effect of the extract of the diphtheritic membrane cannot, therefore, be ascribed to the mere presence of a small amount of albumoses. There is something else which is in all probability of a ferment nature. This dialysed saline extract of diphtheritic membrane also possesses a different local action from that of the albumoses. It may produce simply œdema which will pass off, but in one instance 12 milligrammes injected under the skin of a guinea-pig weighing 710 grammes produced a fever during the first two days of the experiment; the fever subsided on the third day and death occurred on the sixth day. Nothing was found in the body except, at the site of inoculation, a greyish-yellow sloughy-looking area containing no pus, and about half an inch long. The poison had produced a local necrosis of the tissue. These results bring my own work into touch with what has already been done on the chemical products of the bacillus diphtheriæ, or the so-called "Klebs-Löffler bacillus."

Bacillus diphtheriæ.—I do not intend to go fully into the history of the diphtheria bacillus. Suffice it to say it was first recognised by Klebs, first isolated in pure growth by Löffler, and that Roux and Yersin were the first to show that when introduced into the circulation of a rabbit this bacillus produced a paralysis which is progressive and which is, from the description given, of the same nature as that I have already brought before you. Roux and Yersin's results were confirmed by Brieger and Fraenkel. All observers are agreed that the bacillus diphtheriæ is limited to the superficial layers of the membrane, and does not distribute itself over the body. It is not found in the blood or in any of the organs. Similarly, even when subcutaneously inoculated, although it kills the animal, yet its growth is limited to the site of inoculation. This fact, taken with that established by the brilliant researches of Roux and Yersin—namely, that the bacillus produces paralysis—is a very powerful argument that the bacillus diphtheriæ is the *vera causa*, the living contagion, or, as I prefer to call it, the primary infective agent in diphtheria.

Chemical poison isolated by Roux and Yersin.—The chemical poison isolated by Roux and Yersin was of a very virulent nature. They grew the bacillus in veal peptone broth—that is, using peptone as a food for the organism. Such a culture medium is unsuitable for obtaining the products of a pathogenous organism, because it is unlike any liquid medium that exists in the body, and the proteid bodies which are produced by pathogenous organisms are of the same chemical nature as the peptic albumoses which are used in preparing the culture medium. These facts, however, by no means vitiate Roux and Yersin's results. They found that the broth culture, when freed from bacilli, will kill rabbits after producing paralysis, chiefly affecting the hind legs and the respiration. This poison was precipitated by alcohol and by phosphate of lime, and may be dried, and they calculated that as little as 0·0004 gramme was capable of killing eight guinea-pigs of 400 grammes each, or two rabbits of 3 kilogrammes each. Roux and Yersin's conclusions were that this poison was a ferment (diastase), not only from its acting in such small doses, which had a prolonged effect on the body lasting over days, but also from the fact that heating attenuated the poison and boiling destroyed it. At the end of one of their papers they conclude that: "L'infection n'est produite par un microbe envahissant les tissus, mais par la diffusion dans

Digitized by Google

l'organisme d'une substance toxique, *préparée à la surface d'une muqueuse, pour ainsi dire en dehors du corps.*" Brieger and Fraenkel repeated Roux and Yersin's experiments and confirmed them. They attempted to determine accurately the chemistry of the diphtheria product, which they called "toxalbumen"; but their chemical analyses and reactions are quite vitiated by the fact that they had peptone in their culture medium. They found, like Roux and Yersin, that the proteid or mixture of proteid precipitated from the culture medium by alcohol acted in very small doses, such as from 5 to 20 milligrammes, when injected into the circulation of an animal; but they made the hasty conclusion that a poison like this diphtheritic product existed in all infectious diseases. I have obtained the products of the bacillus diphtheriæ[1] by using as a culture medium a from 1 to 2 per cent. solution of alkali-albumen in broth prepared from beef, without the addition of peptone. After from twenty-two to thirty-two days it is found that the bacillus has transformed the alkali-albumen into albumoses, which give the reactions of proto- and deutero-albumoses. Small quantities of the organic acid were also obtained. A single large dose of these albumoses, equal to 0·115 gramme per kilogramme of body weight, produced a weakness of the hind limbs on the first day, and to a less extent of the whole body; this passed off, but the rabbit lost weight for ten days or more. It afterwards regained its weight, and when killed on the hundredth day it was fat and well nourished. The microscopical examination revealed the same changes as have been described as following the injection of a single dose of the albumose found in patients dead of diphtheria. The heart showed advanced fatty degeneration, and there was well-marked degeneration of the phrenic nerve and the nerve to the vastus muscle; the only two nerves examined.

Physiological action of multiple doses of the albumoses formed by the bacillus diphtheriæ.—One rabbit received intravenously three doses of the albumoses, equal to 0·111 gramme per kilogramme of body weight. There was well-marked fever, which subsided after the last dose; but beyond this there were no symptoms. The animal was killed on the thirtieth day. The heart, diaphragm, and triceps brachii were found fattily degenerated; while portions of the vastus internus, semi-membranosus, semi-tendinosus, and gastrocnemius were found normal. The phrenic and the nerves to the muscles mentioned (with the exception of that to the semi-tendinosus) show a degeneration precisely similar to that which has been described as following the intravenous injection of the albumoses found in the tissues of diphtheria patients. One or more branches of each of the motor nerves mentioned were found degenerated, but there were only a few ruptured axis cylinders, and no well marked Wallerian degeneration, explaining why no paralysis was observed in the animals during life. A larger dose than the one under consideration produces the same symptoms that follow the injection of the albumoses from diphtheria patients. Thus, an adult rabbit received three doses of the albumoses of the bacillus diphtheriæ (on successive days), equal in all to a dose of 0·169 gramme per kilogramme of body weight. After the first two doses there was high fever; but after the third a slight depression of temperature occurred which lasted two days. Severe watery diarrhœa set in, and lasted until the ninth day. The wasting was very rapid until the twelfth day, when the animal had lost a quarter of its original weight. It afterwards gained slightly in weight. A general weakness of the muscles was present on the fourth day, but no definite paralysis until the eleventh or twelfth day, when the hind legs were distinctly affected, and the animal dragged one leg after the other. The paralysis progressed, but the animal is still alive. The tendon reflexes were normal up to the ninth day, when they began to diminish, and on the seventeenth day they could scarcely be obtained. From these experiments it is clear that—(1) the bacillus diphtheriæ forms, from proteids, products of the same chemical nature as those found in the bodies of patients dead of diphtheria—viz., albumoses and an organic acid; (2) the albumoses formed by the bacillus in artificial cultivations have, in single and multiple doses, the same physiological action as those found in cases of diphtheria in man—this action is the production of fever, of diarrhœa, and of loss of body weight, and of a progressive paralysis of the muscles dependent on a degeneration, of the peripheral nerves; (3) the bacillus diphtheriæ is therefore the primary infective agent in diphtheria. The relation of Roux and Yersin's poison to those I have described as present in the bodies of patients suffering from diphtheria is made clear from the fact that a much more virulent poison exists in the diphtheritic membrane than in the body of patients suffering from diphtheria; so that we can bring into a table the chemical pathology of diphtheria into the same line as that of anthrax, and head all the changes by the term "Diphtheria digestion."

Diphtheria Digestion.

Primary infective agent.	Secondary infective agent.	Digestive products.	—
Bacillus diphtheriæ	Diphtheria ferment (Roux and Yersin's poison) in membrane	Hetero-albumose, Proto-albumose, Deutero-albumose, Organic acid	In membrane. In body.

It is evident that the primary infective agent in diphtheria is the bacillus diphtheriæ; that this liberates in the membrane a ferment which, when absorbed, digests the proteids of the body forming albumoses and an organic acid. These digested products are the agents in producing death, in causing fever, the depression and the paralysis which follow diphtheria. It is clear from the cases of diphtheria which have been described that the diphtheria products found in the body do not all come direct from the membrane. In Case 1, for example, only small flecks of membrane were found in the larynx, and yet in the body a large quantity of the diphtheria products were discovered. The large amount of albumoses and organic acid found in the spleen also shows that something more than absorption of albumoses is going on. There is no reason to suppose that these albumoses merely accumulate in the spleen, and their specific physiological action shows that they are foreign to the organism. It is more probable that the ferment absorbed from the membrane digests the more or less stagnating proteids in that organ, and we know indeed that the spleen contains a proportionately larger quantity than the blood of bodies formed from proteids, such as uric acid, xanthin, &c.

ABSTRACT OF THE

Milroy Lectures

ON THE

PHYSICAL AND MENTAL CONDITION OF SCHOOL CHILDREN.

Delivered at the Royal College of Physicians, London, March 8th, 10th, 15th, and 17th,

BY FRANCIS WARNER, M.D., F.R.C.P. LOND.,
PHYSICIAN TO THE LONDON HOSPITAL.

LECTURE IV.

The bearing of this inquiry on State medicine, education, and the care of children.—The State becomes heavily burdened by the defectively made portion of the population, which probably tends to accumulate under extensive emigration, which leaves with us the weak, tending to pauperism, starvation, vagrancy, and crime, a large body of "unemployed," and others capable of earning only small and varying wages; the field for recruiting the services is also limited. Were this lower stratum improved, it would pave the way for social amelioration, higher education, better and more valued wage-earning, and less social failure. It must be remembered that these feebly gifted children are confined to no social class, and appear more numerous in the upper grades. The nation collectively is but the aggregate of its components. These observations show the harm that probably arises from exempting the feebly gifted and defective children from all education,

ABSTRACT OF THE

Milroy Lectures

ON THE

PHYSICAL AND MENTAL CONDITION OF SCHOOL CHILDREN.

Delivered at the Royal College of Physicians, London, March 8th, 10th, 15th, and 17th,

BY FRANCIS WARNER, M.D., F.R.C.P. Lond.,

PHYSICIAN TO THE LONDON HOSPITAL.

LECTURE IV.

The bearing of this inquiry on State medicine, education, and the care of children.—The State becomes burdened by the defectively made portion of the population, which probably tends to accumulate under certain conditions, which leaves with us the weak, feeble, and "unemployed," and others capable of earning only low and varying wages; the field for recruiting the service is so limited. Were this lower stratum improved, it would pave the way for social amelioration, higher education, better and more valued wage-earning, and less pauperism and failure. It must be remembered that these feebly gifted children are confined to no social class, and appear as numerous in the upper grades. The nation collectively is the aggregate of its components. These observations

because they are unfitted to compete, even in school, with the average and the normal. It is, then, as important concerning a certain locality or sanitary area to know the average condition of the children as the rate of mortality. Mal-development has been shown, as far as the facts go, to be a potent factor in predisposing to both mental dulness and low nutrition, two evils worth combating. It is not solely for the purpose of attaining a condition of the people with a smaller percentage of badly made heads, palates, ears, noses, or other bodily defects that a strong effort is called for, but that in removing the causes of such defects we may lessen the average of mental feebleness and low nutrition coattendant. The ends which it is desired to attain through State medicine are to improve the average development, nutrition, and potentiality for mental faculty, and thus to lessen crime, pauperism, and social failure by removing causes leading to degeneration among the population.

Correlation, or the relations of physical and nerve signs to low nutrition and mental dulness.—In a table given the number of cases presenting each sign has been shown, and in the more important instances, where the number of cases in which the sign was observed was large enough, or when the intrinsic value or interest of the sign seemed to call for it, the correlation has been added, showing the number of cases presenting the sign who were also registered as presenting "low nutrition," "abnormal nerve signs," "mal-developments," or "mental dulness" respectively. These correlations have been put into the form of percentages in a table. It is not wished to represent the percentages as having an absolute value of correlation to the sign which may be applied to an individual child. The correlation for some signs is probably of little value on account of the small number of cases observed; but it is given as illustrating that each physical or nerve sign has a correlation average with mental dulness, nutrition, &c. When the correlation is on a small number of cases the need of further observations in this direction is indicated. The percentage form is useful, as indicating that some generalisations drawn from large groups of cases apply equally to the individual signs characterising the group. Thus defects in development have a higher correlation with abnormal nerve signs in boys than in girls, but as to nutrition and mental dulness the girls suffer most. As a contribution towards the etiology of defective development I arranged the 3704 development cases seen among 34,991 children according to their distribution in twenty districts; this is shown in Table 6 of the interim report. The percentage of these development cases taken upon the number of children seen in each district respectively is very unequal, being high in the western district of Kensington and Chelsea (12·6 per cent.) and lower in the poorer schools of Islington (7·4 per cent.). This table also gives the percentage distribution of the principal defects registered, taken in two ways: (1) Upon the number of children seen; (2) upon the number of development cases. If such observations are confirmed by further experience, this method of arranging the facts may afford evidence upon the causes in the district tending to produce defects in development, and, possibly, for determining the particular kind of defect most prevalent. Observations of the 1363 development cases in Poor-law schools, which are drawn from certain areas, are similarly given in Table 8, and a table has been prepared for comparison showing conditions of the children in day schools for areas corresponding to the unions. In certain districts the ratio of boys and girls presenting some conditions is not the average. As a preliminary to try to determine the means that may be used to lessen the physical causes of mental dulness I have given a table of the conditions and groups of conditions accompanying it; and have determined, as far as the present work goes, the correlative value of each sign in development and nerve action observed, as well as the distribution of these signs in certain areas or districts and in certain classes of schools, and in the nationalities. The percentage of mental dulness rises from 35 for development cases without nerve signs to 43 when both are present, reaching 44 when the mal-development is accompanied by low nutrition and abnormal nerve signs.

Development cases considered in relation to sex and residence.—If we take 100 boys and 100 girls with defects in development from among the 50,000 children seen, we shall find many of them with abnormal nerve signs, low nutrition, and mentally dull. Following the experience gained, the following estimate may be given, showing the probable results of placing them first in a day school and then in a resident school.

IN THE DAY SCHOOL.

100 boys and 100 girls, with defects in development.

Boys' Side.		Girls' Side.	
Nerve cases	50	Nerve cases	47
Nutrition low	23	Nutrition low	38
Reported dull	38	Reported dull	40
Total	111	Total	125

IN THE RESIDENT SCHOOL.

100 boys and 100 girls, with defects in development.

Boys' Side.		Girls' Side.	
Nerve cases	62	Nerve cases	52
Nutrition low	16	Nutrition low	20
Reported dull	40	Reported dull	44
Total	118	Total	116

It is thus obvious that residence, contrasted with home life and day school, produces marked effects, different among boys and girls. On both sides of the resident school nutrition becomes higher, more markedly with the girls. Nerve signs increase with residence, especially with boys. Mental dulness increases with residence slightly, more so among the girls. The loss and gain from putting 100 boys and 100 girls with defects in development in resident schools may be represented thus: Fewer cases of low nutrition by seven boys, eighteen girls; more cases of abnormal nerve signs by twelve boys, five girls; more cases of mental dulness by two boys, four girls.

Assessment of results of intellectual and physical training in a school, with allowance for the physical condition of the children.—Having obtained a report on the physical condition of the children in a school, we may proceed to estimate the number of dull children and the number with nerve signs to be expected, upon allowance for the material in a school; the estimate is founded upon the conditions seen and the average experience of 50,000 children, the allowance being made upon the development cases and nerve cases, an allowance for low nutrition could be added. There are two results of physical training which characterise it as satisfactory: (1) In cases of defective development to remove or prevent abnormal nerve signs; (2) in children of normal development to prevent, or at least not to produce, nerve signs. Thus, taking the development cases in a school, a high percentage of abnormal nerve signs among them is against the effects of the training; and a high percentage of nerve cases without defects in development suggests that the training is not good. So also in each case a high percentage of mental dulness shows want of adaptation of methods of teaching to the special requirements of the children. A form is given (see report) upon which the principal facts observed in a school may be recorded; from these estimates may be made. We may estimate as dull children: Of development cases with nerve signs—boys 43 per cent., girls 43 per cent; without nerve signs—boys 33 per cent., girls 39 per cent.; of nerve cases without development defects—boys 37 per cent., girls 41 per cent. We may estimate as the average number of cases with nerve signs: Of the development cases—boys 55 per cent., girls 49 per cent.; as presenting nerve signs without defects in development of the total number of children seen—boys 5 per cent., girls 4 per cent. The work that has already been done, and the report from which extracts are given, afford a considerable amount of evidence to the following propositions: *A.* It is practicable to inspect, report upon, and classify the children seen in a school by means of facts seen and the teacher's report. Evidence of scientific value is thus obtainable of importance to the State, to education, and to philanthropic efforts. *B.* The average child material in a school or district may be determined. The conditions of development and the nerve signs vary much in different schools; as to the latter, observation suggests that adapted methods of training may remove them. *C.* The correlation of visible signs with low nutrition and mental dulness has in many cases been demonstrated. *D.* Ill-made and feeble children tend to gravitate to the Poor-law and certified industrial schools and to the lower standards of day schools. The want of due provision for feeble children in day schools, and in many cases their exemption on medical certificates, tend to throw such cases upon the care of the State, and many become degraded. *E.* Feebly gifted children, the paralysed, and in some cases the epileptic, may in many cases and in limited numbers be educated in day schools if better provision for them is not afforded.

PULSATIONS AND MURMURS IN THE GREAT VEINS OF THE NECK:

THEIR PHYSIOLOGICAL AND CLINICAL SIGNIFICANCE.

By SYDNEY RINGER, M.D., F.R.S.,
AND
HARRINGTON SAINSBURY, M.D., M.R.C.P.

ON the importance of considering separately the two phenomena pulsations and murmurs we have already insisted in a recent paper in THE LANCET.[1] In the same paper we discussed at length the subject of venous pulsation. Stated very briefly, we pointed out that pulsation in the great veins at the root of the neck was a normal occurrence in animals, as demonstrated by physiologists; that it was of probable occurrence as a normal event in man, though for the most part not visible through the integuments in quiet states of the circulation; that, however, in most cases of marked anæmia, especially in women, venous pulsation was very evident at the root of the neck, particularly in the recumbent posture; that such venous pulsation (of anæmia) must be regarded as physiological rather than pathological, since it had not the significance of a distended right side of the heart; that important time relations distinguished the venous pulsation of health and of anæmia from the venous pulsation attending intra-thoracic disease with distended *right* heart, the former being characterised by its main pulsation being presystolic, the collapse of the vein being systolic, the latter, by the coincidence of its main pulsation, with the ventricular systole. We showed at the same time that intermediate cases must arise in which the determination of the time relations of the pulsations would be difficult, if not impossible, such cases standing on the borderland between health and disease; but we urged that these indeterminable cases did not make it any the less imperative that in each case of venous pulsation we should attempt to discover whether it was a physiological or pathological sign.

We have now to discuss the question of murmurs in the veins of the neck. Without entering at all fully into the subject of venous murmurs in general we may set down a few points of importance. First, venous bruits are to be sought in the larger venous trunks, since the blood currents gathered together in these from extensive tributary areas will be flowing in greater volume and swiftness. Next, such venous trunks being, with few exceptions, contiguous to arterial trunks,[2] we must bear in mind the possibility that a given murmur heard over the course of a vein may really be of arterial origin or that the murmur or murmurs may be both venous and arterial. This last involves the necessity that we should know how to distinguish a venous bruit from an arterial bruit. The following points will help us to do this. The venous bruit has the character variously described by the terms, "rumbling," "purring," "humming," "cooing," or even "whistling," and it is more or less continuous, occupying the greater part or the whole of the cardiac cycle. The arterial bruit, as heard in the vessels of the neck, is a much higher pitched sound, and more of the nature of a whiff or bellows sound, and it is essentially intermittent.[3] This intermittence depends upon the jerky arterial flow, just as the relative continuous character of the venous bruit depends upon its even flow.[4] The venous bruit, especially in the neck, gives the impression of greater superficiality, and in listening for it we should employ comparatively light pressure. It is best to begin with very light pressure, and to increase this gradually till the murmur appears. The vibrations causing the venous bruit are in many cases so superficial and so coarse that the finger laid very lightly on the skin detects them as a thrill. The arterial bruit requires deeper pressure for its detection. These facts accord with the anatomically deeper position of the artery in the neck and the higher tension within this vessel, necessitating more forcible compression. If a murmur at the root of the neck appear on deep pressure only, its arterial origin becomes more probable.

The venous bruit is in general controlled or wholly abolished by distal compression of the vein—i.e., anywhere along the course of the vein above the point of auscultation: The force needful for this is in general light and wholly inadequate to compress the artery. In this procedure we have a means, as Hope says, "of convincing the most sceptical that the seat of the murmur is really in the vein" (p. 105). Listening over the bulb the internal jugular may be compressed in any part of its course above, provided that we obliterate the vessel. Hope has given very fully the precautions requisite in investigating venous bruits, and in particular he has drawn attention to what may be described as the fickleness of the bruit—e.g., at one moment it is heard well, at another it has altered or nearly disappeared. It is probable that this fickleness depends very greatly on slight variations in pressure on the veins as by the stethoscope, or even by the stretch of the skin or muscles due to an altered position of the head and neck.[5] Further, various bruits possess the character, frequently observed, of gradually increasing or swelling during auscultation. Thus when first listened to the bruit may be ill heard, but it gradually gains in loudness; soon, however, reaching a maximum, which it maintains so long as the conditions of pressure and stretching of the vein are maintained. Hope's explanation of this phenomenon is undoubtedly the correct one—viz., that it results from a gathering congestion in the veins distally to the site of compression by the stethoscope.[6] We have very occasionally observed the same thing when attempting to arrest the bruit by pressing with the fingers distally on the vein of the same side of the neck; and we have been forced to conclude that, the pressure not having been quite properly placed, we had narrowed but not obliterated the vein, and so had caused congestion above the seat of pressure. Such congestion would of course mean an increased head of pressure. Certainly such an explanation must account for another and frequent observation which we have made—viz., that pressure on the opposite side of the neck, say the left, in the region of the internal jugular, will cause a gradual swelling out of the bruit heard on the right side. This came out repeatedly and unexpectedly whilst timing the phases of the venous bruit by taking the pulse in the carotid of the opposite side of the neck. Compression of one internal jugular must cause congestion in the veins of the head and neck, and cause the blood to be hurried through the still patent jugular of the opposite side; but the congestion does not reach its maximum at first, and hence the swell in the bruit. We have once or twice had confirmation of this by observing that pressure on one internal jugular would cause the veins of the opposite side of the neck and their pulsations to become more manifest. Lastly, in connexion with this point, it will be noticed that after the breath has been held for a short time the venous bruits receive a sudden increment with the first respirations taken—i.e., with the unloading of the veins congested during the cessation of breathing; this, however, is hardly an example of the swelling of the sound.

We have said that the venous bruit will arise most frequently in the large venous trunks; we may go further, and say that practically it does not arise in the smaller veins, and that any bruit heard peripherally—e.g., in hand or foot or elsewhere away from large trunks—will be arterial, and not venous.[7] The veins in which bruits are audible, are, according to Walshe, the external and internal jugulars on both sides or on one side only, in the latter case most frequently on the right side; the subclavian veins, the femoral, the axillary, the superior cava, and the innominate veins; certain abdominal veins; the pulmonary veins and the superior longitudinal sinus, in particular at its termination in the torcular Herophili.[8] This arrangement is

[1] Nov. 28th and Dec. 5th, 1891.

[2] The exceptions to the contiguity of venous and arterial trunks are to be found in the intra-cranial venous sinuses. No artery accompanies these, and, accordingly, where in such sinuses a bruit is heard, we have the proof of the sole origin of the murmur in the vein. These sinuses, moreover, are incompressible by the stethoscope, and hence we get the further demonstration that the bruit may be a natural phenomenon, independent of any compression of the vessel in which it is heard.

[3] See Hope: Diseases of the Heart, fourth edition, pp. 125 and 103.

[4] We shall see, however, that intermission or remission becomes a character of venous bruits in veins near the heart.

[5] Even so slight an act as that of swallowing influences, and may momentarily suspend, the bruit; cf. Hope, op. cit., p. 103, and more recently Murray, THE LANCET, vol. ii. 1887, p. 204.

[6] P. 106.

[7] Cf. the bruit heard in anæmia over the palmar arch or over the radial artery, or the bruits met with occasionally in these situations, and elsewhere in aortic regurgitation. These bruits possess markedly the intermittent and whiffing characters of arterial bruits.

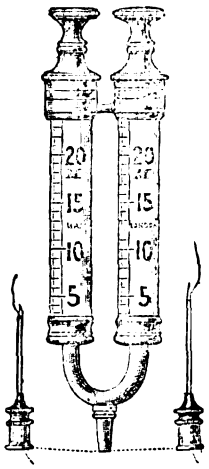
in the order of frequency of occurrence of the phenomenon, and it will be observed that the external and internal jugulars of the right side stand first. Of all sites of the venous bruit the right internal jugular at its lower end is the most favoured; this is universally conceded. Certain anatomical facts give the explanation—viz., the dilatation of the lower end of the vein to form the bulb, the continuance by the right innominate of the same course (approximately) as that of the internal jugular, the attachment of certain fasciæ to the vein which prevents the complete collapse of the vein: every treatise on the subject insists on these points. Stated precisely, the best position for listening to the bruit will be found to be just between the two heads of attachment of the sterno mastoid to sternum and clavicle, or, a little outside this, more directly over the clavicular attachment.[9] Is the venous bruit heard in health, and what is the comparative frequency of its occurrence in health and in disease? We do not propose to discuss these questions, for we think the general verdict is fairly definite—viz., that both as to frequency of happening and intensity of degree the venous bruit belongs especially to anæmia, however this anæmia may have been brought about.

(To be concluded.)



TREATMENT OF GOITRE BY IODINE, MERCURY, AND POTASH INJECTIONS, AND RADICAL CURE BY OPERATION.

BY GEO. J. O'REILLY, M.K. & Q.C.P.I., L.R.C.S.I., &c.

FOR some years I have been using iodine, mercury, and potash injections for reducing glandular swellings with much success. Amongst them were cases of goitre, and in not one has there been trouble of any kind caused by the injections. The case I am about to report is one of a goitre of an enormous size, estimated to weigh some six pounds or more. The tumour was of thirty-six years' growth, as the patient remembers an enlargement of her neck since she was six years old; she is now in her forty-second year. It gave her much trouble for years, producing great difficulty of breathing, especially when she lay down at night (almost suffocating her), and of late entailing the necessity of having means ready to obtain boiling water, to inhale steam, so that she might get her breath at all; in fact, her life was a misery. She consulted me in September of last year to know if anything could be done to relieve her, when she gave me the above short history, with the addition that for four years she had consulted no one about it, as she was then advised never to have it interfered with in any way, as it would be most dangerous, and that very likely it was a cancerous growth; and that as all previous external remedies had failed, it was better and safer to leave well alone. I examined the growth very carefully, and came to the conclusion that it was an ordinary cystic tumour of the thyroid gland, which was very much enlarged, and I saw nothing to make me think it was of a cancerous nature. I explained to her the treatment she would have to undergo, and expressed myself hopefully that it would give her much relief and make her future condition considerably easier. She willingly consented to put herself in my hands and submit to the treatment I proposed—viz., the injections of certain drugs such as I had used in other similar cases. On Oct. 3rd I made the first injection of a solution of the perchloride of mercury, using a glass syringe with asbestos piston and the finest needle, made for me by Messrs Maw, Son, and Thompson. (See Fig. 1.) On this occasion I injected in three places where I felt cysts; this I repeated for six days in succession. After that there was a decided improvement in her breathing; she could sleep comfortably without coughing (which before had been incessant and most irritating), nor had she any other discomfort. After this I made injections only twice a week, Tuesdays and Fridays, alternating the mercury solution with one of iodine, a re-sublimated solution, and one of permanganate of potash (specially prepared for me by Messrs. Corbyn and Stacey of Holborn), sometimes injecting two of the solutions in different places on the one occasion. In all, I made some seventy injections, and, with two or three exceptions, there was not even discolouration of the skin. This treatment continued until the end of November, when the tumour was reduced to about one-third of its original size; during this time the patient was in excellent health, and doing with comfort her household duties.

The question now arose as to the radical cure by removing the entire tumour, which was now very consolidated and hard. I explained to her that it was a dangerous operation, as the growth was of such long standing, and as there were sure to be adhesions to all the deep structures of the neck. She evidently was anxious that I should undertake it, and I readily acquiesced with her wishes. I made all my arrangements, and on Dec. 3rd I operated, and removed the entire right lobe of the thyroid gland in its capsule, which weighed over two pounds. The steps of the operation were as follows: I made an incision about six inches and a half in length, reaching from the under jaw to the clavicle, and over the central part of the growth, and carefully dissected back the integuments and adipose tissue, and cut through the platysma and the anterior border of the sterno-mastoid muscle. I then laid bare the anterior surface of the tumour; but finding the wound was not large enough to separate the posterior surface from its deep attachments, I enlarged it obliquely towards the right ear, and this gave

FIG. 1.

The "double-barreled" syringe, as represented by the woodcut, is so designed that by one insertion of the needle two purposes are effected. If the tumour is cystic, a quantity of the contained fluid can be withdrawn for examination; the other barrel, having been previously filled with the solution for injection, can then be used without removing the needle. I have found in many cases where the cyst was very much distended, that it was advisable, and even necessary, to withdraw some of its contents before introducing the solution, as by so doing there is no pain or fear of producing any inflammatory condition. In cases of suppurating glands it is of supreme importance, as they are gradually emptied, and in consequence no unsightly marks are left.

me ample space to grasp the tumour in my hand; then with the handle of an ordinary scalpel I was enabled to tear through its attachments. It lay right on the internal carotid artery and jugular vein. There was considerable hæmorrhage from large vessels that had to be torn through; these I torsioned, and where necessary tied with gut. The isthmus was secured and tied in two places, and then divided with blunt-pointed scissors without any loss of blood. The inferior thyroid artery gave me some trouble, as it was so deep down in the supra-clavicular fossa. In order to avoid including the recurrent laryngeal nerve in the ligature, an attempt was made to separate the artery from the other structures attached to the inferior angle of the tumour. In doing so a large vein was torn across. The bleeding for a moment was very great, but the vessel was almost immediately secured. The artery was then tied, cut through, and the tumour removed in its entirety. No bleeding of any moment took place. All oozing points were nipped in a torsion forceps, and the wound swabbed out for some minutes with iodine water, and left open so as to allow the cold air to act as a natural hæmostatic. When all oozing had ceased I brought the parts together, leaving a drainage-tube (about No. 12 catheter size) at the bottom of the cavity.

The operation was done under fairly good antiseptic measures, and the wound dressed with antiseptic (mercurial) gauze and iodoform wool pads. The wound healed up without any trouble. There was slight sanguineous discharge from the drainage-tube, which I removed on the third or fourth day. There was no formation of pus, and I believe the wound would have healed up by first intention had I left out the drainage-tube altogether. The operation from

[9] Parrot (Archives Générales de Médecine, 1867, p. 654): The stethoscope must be moved outwards or inwards till the exact spot has been found.

Digitized by Google

the first incision until the dressings were completed lasted one hour and twenty minutes. The patient remained under the anæsthetic for two hours after the operation; when she awoke she was slightly sick, but it did not disturb the dressings or cause any bleeding. When I again visited her in the evening she said she was quite comfortable and not in much pain, and she was well able to take the liquid nourishment ordered. The temperature reached 99·6° on the evening of the second day after the operation; it then became normal, and remained so throughout the convalescence. She was able to sit up in bed on the fifth day, and was up on the ninth day. All the stitches were removed on the seventh day, when the wound was practically healed up. With the exception of some opening pills on two occasions, she had no medicine either before or after the operation. She has made a perfect recovery. The wound is now only some two inches and a half long, and there is nothing unsightly to be seen. She is able to perform her usual avocations with greater comfort and in better health than she ever remembers to have enjoyed. I therefore consider that the injections are of immense value in reducing the size of the tumour, and, consequently, in giving much relief at once; and, again, of infinite value in consolidating the growth, so that, in case of operation, it can be easily detached from the surrounding tissues by the fact of the operator being able to grasp it firmly in the hand while separating it from the deeper parts. I may add that the left lobe of the gland was enlarged to about six times its usual size; this was injected several times, and also shared in the general reduction that took place before the operation. It appeared very large after the other portion was removed, but it is now its normal size. The strengths of the solutions of iodine, mercury, and potassium that I used in this, as in all my other cases, vary from 1 in 10,000 to 1 in 500. In no case where I have used them in glandular swellings of the neck or elsewhere have they caused suppuration or left an unseemly mark, not even in very strumous children.

The engravings are taken from photographs. Fig. 2 represents the patient before the injections were used, Fig. 3 after two months' treatment by injection and four days before the operation, and Fig. 4 is from a photograph taken some weeks ago. The marks of the sutures have now entirely gone, and a cicatrix some two inches long is only apparent. I append the pathological notes made for me by Mr. Targett, curator of the Pathological Museum of the Royal College of Surgeons, who has also kindly prepared the tumour as a specimen for that museum.

FIG. 2.

"*Description of specimen of tumour of thyroid.*—The tumour consists of the right lobe of the thyroid body, with the attachment of the isthmus. When fresh it weighed thirty-three ounces. Its external surface is marked by a deep longitudinal groove, due to the sterno mastoid muscle. It is covered by a tough fibrous capsule, which is permeated with numerous widely dilated veins. After preservation in spirit the tumour measures six inches and a half from above downwards, and four inches and a half from side to side, while its greatest thickness is three inches. On section it is seen to be made up of a collection of large cysts, together with a small amount of intervening solid material, and two or three encapsuled adenomata. Of these adenomata the largest is about the size of a Tangerine orange, and the section shows that

FIG. 3.

it has undergone colloid degeneration. Occupying the centre of the preparation is an oval cyst, two inches in its longest diameter, the wall of which has become partly calcified. The remaining cysts are of various sizes, but all smaller than the above. The septa between them are in places so thin that they have become perforated, and thus intercommunication has been established. The cysts contained altogether five ounces of blood-stained fluid. Histological examination of the solid material between the cysts

FIG. 4.

shows the normal structure of the thyroid body somewhat denser than usual, and without colloid change. The walls of the cysts are composed of very dense fibrous tissue, and are devoid of lining membrane. The cysts are probably due to dilatation of follicles, and the layer of cubical epithelium by which they were originally lined has been completely destroyed."

THE TREATMENT OF TRICHIASIS AND ENTROPION.

BY W. A. McKEOWN, M.D., M.CH.,
SURGEON TO THE ULSTER EYE, EAR, AND THROAT HOSPITAL, BELFAST.

THE unsatisfactory nature of the treatment of these affections may be judged by the large number of operative procedures of one sort or other which the writers of handbooks of diseases of the eye think it necessary to detail. There can be no question about the ingenuity displayed, but as a rule it is not directed to simplicity of method. I find in Swanzy's excellent handbook no less than eight chief operations for trichiasis and organic entropion and four for spastic entropion. In Meyer's book there are about a score of operations described and more mentioned. These books purport to be written chiefly for students and general practitioners, but even to one familiar with ophthalmic surgery it requires attentive reading to grasp all the technicalities. The operations referred to may be objected to on one or more grounds. First, unnecessary destruction of tissue; secondly, complexity and difficulty in execution; and, thirdly, uncertainty. I will not discuss or even name these different operations, but proceed to describe a method which I have practised extensively, and which I think will supplant all other methods. The operation is as follows. First stage: If the upper lid is to be operated on, introduce the smooth handle of a dessertspoon under the lid, to protect the eyeball and support the lid; let the assistant hold it whilst the surgeon steadies the lid on the handle with the left hand, and with the right hand introduces a Graefe's cataract knife at the margin of the lid between the eyelashes and the Meibomian glands, either close to the punctum or at the outer canthus; then push the knife beneath the skin about as far as the orbital margin, and by to-and-fro motion cut along the whole of the lid margin until he has the lid split into two layers, the outer layer containing the skin and eyelashes, the inner layer the cartilage, Meibomian glands, &c. If the skin and hairs can be moved freely upwards, the section has been properly made; if not, blunt-pointed scissors should be passed into the section, and any tissue preventing free motion cut. Second stage: The skin and eyelashes are glided upwards so as to expose about two lines of the cartilage, and are to be secured in their new position as follows. A curved needle with a strong silk iodoformed thread is to be passed through the skin at the middle of the lid about two lines from the eyelashes, then through the cartilage, emerging on to the conjunctival surface about four lines from the margin, and then the needle is to be passed back again through the cartilage and skin, coming out a line or so from the original point of entry on the same horizontal line. A thread is then passed in the same way near the outer and inner canthus respectively. The skin layer and the cartilaginous layer of the lid are now secured by three loops of thread in such a way that the lashes must be displaced upwards far from the eye. Each thread is tied with moderate tightness over a tiny roll of lint or cotton-wool. Adhesion of the two layers in the new position quickly takes place. It is evident that at the outer and inner corners of the section the hairs will not be so much deviated as at the centre, and if the surgeon should think there was any special tendency to a turning in of the hairs at these parts he should make a small vertical incision through the skin, and by a suture at each corner elevate the eyelashes to the desired extent. Third stage (grafting): At one time I followed von Milligen's method by taking a graft from the mucous membrane of the lip, but I found that the taking of such a graft was not a very expeditious procedure. I have for a considerable time taken the graft from the back of the ear, and for ease of performance and perfection in result I do not think it could be surpassed. I expose the back surface of the ear, pass a Graefe's knife under the skin for about an inch, then cut out on one side, and separate the attached side by fine scissors. I place the graft on the back of my left hand, and with fine scissors remove all subcutaneous tissue (this can be done quickly); remove any blood with lint soaked in warm boracic acid lotion, and immediately apply the graft to the exposed surface of the tarsal cartilage, previously cleared of all clots, and likewise cleansed with boracic lotion. I may remark that I think solution of perchloride of mercury not desirable in grafting operations because of its coagulating power. I adjust carefully the graft by a probe, and do not proceed to the dressing until it seems to be pretty adherent. Fourth stage (the dressing): Apply a little strip of lint, saturated with warm iodoform and vaseline ointment, over the graft, and on the top of that a piece of lint to cover the whole eyelid, similarly saturated, then dry lint and bandage. Both eyes are bandaged. The patient is put to bed and not disturbed for four days. At the lapse of that time the stitches are removed, but the eye operated on is bandaged for three or four days more. It may be observed that I couple trichiasis and entropion, and write of them as if to be treated by one operation. If the cartilage be thickened or distorted, it is obvious that with such a free exposure of the cartilage the surgeon can do anything with it; he may groove it or pare &c. as surgeons have recommended, but the grooving, paring, &c., would be only a small incident in the general operation, and hardly worth naming as a separate or modified method.

The features of this operation are: 1. That no skin or other tissue is destroyed or removed, save in thickening or distortion of the cartilage. 2. Expedition in performance. 3. Certainty of immediate result, and no liability to relapse. 4. Its applicability to all sorts of trichiasis and organic entropion. I have not described the operation for trichiasis of the lower lid, as there is but slight variation. As to what is called "spastic entropion" of the lower lid in old persons, arising chiefly from relaxation of the skin, I see in the text-books, old and new, several operations described. The trouble, however, may be sufficiently relieved without any operation at all. All that is necessary is to put a little pressure on the lower lid, and that may be conveniently done by a spectacle-frame of such a form as to press on the lower lid, or, if that cannot be found, by putting a ledge on the lower edge of a frame. For this suggestion I am indebted to my brother, Dr. McKeown of Manchester, who has already put it in practice. Patients prefer this simple and effectual method to any operation. When only a few hairs are deviated I see in some books of repute that it is recommended to excise the hairs with the skin. I have never done this, but I have seen cases in which it was done with disastrous results. Even when a few hairs are faulty it is commonly better to operate on the whole lid, as I have described. It seems a more formidable operation, but in the matter of personal appearance it is far superior to the seemingly simple excision. Should I wish to get rid of a few hairs and not to do the complete lid-splitting, I introduce the knife between the faulty hairs and the Meibomian glands, bring the point out through the skin two or three lines from the margin, then cut on till I have passed all the hairs to be dealt with, and cut out on the skin surface. I thus have a little flap which I can evert. I snip out the roots of the faulty hairs, then replace the little flap, and secure it by suture. Neither skin nor margin of the lid is injured.

Belfast, Ireland.

ATTEMPTED POISONING BY CARBOLIC ACID.

BY E. C. KINGSFORD, L.R.C.P.LOND., M R.C.S.

THE following case of attempted poisoning by carbolic acid is, perhaps, of even greater interest than that reported by Dr. Greenway in THE LANCET of Aug. 29th, 1891, p. 485, in that the acid was not diluted, and that no treatment was attempted till more than seven hours after the "accident."

J. G——, aged thirty-six, was admitted to the Bolton Infirmary at 2 P.M. on Aug. 22nd, 1889, under the care of Mr. G. A. Patrick, with a report that he had poisoned himself with carbolic acid. He was quite unconscious, but rolling about as if in great agony, and breathing in an irregular and spasmodic manner, each expiratory effort being accompanied by a loud bellowing noise; his extremities and surface were cold and bathed in a clammy perspiration, and the pulse could scarcely be felt anywhere. The tongue and inside of the mouth were covered with a thick white slough, and the skin from the right corner of the mouth to the chin was excoriated where some of the fluid had trickled down. Ineffectual attempts were made to force him to swallow

Digitized by Google

oil &c., and, after a hypodermic injection of apomorphia had failed to act, a soft œsophageal tube was passed in order to empty the stomach; this, however, could not be effected on account of the openings in the tube becoming plugged. About fifteen minutes after the exhibition of the apomorphia, and while the tube was being manipulated, the patient vomited, bringing up about a pint and a half of light-brown, curdy, tenacious material containing lumps of apparently partially digested food. This at the time was supposed to be the remains of a recent meal, and unfortunately was not preserved. Great difficulty was found in soothing the patient and in overcoming the effects of shock; but he eventually made a good recovery, and was able to leave the hospital thirteen days after his admission. The mouth was still somewhat sore, but he could swallow without difficulty. Two months later, when seen at the Quarter Sessions, he was apparently quite free from the effects of the poison. On account of his mental condition he was handed over to the care of his friends, and, as the police have not heard anything of him since, it is to be presumed that he has had no further trouble. The history of the attempt on his life, as received from the man himself and from others, is as follows:—He had been out of work for some time, and for several months had suffered from mental depression and hallucinations, imagining that his dead wife frequently appeared to him, upbraiding him for previous cruelty, although, according to the account of his neighbours, he had always been a good husband. Four months previously to this date he determined to do away with himself, and for this purpose procured three ounces of strong carbolic acid; but, changing his mind, he carefully put it aside for future use. On Aug. 21st, his hallucinations having become more persistent, he decided to take the poison. After a light meal of bread and tea at about 5.30 P.M., he spent the evening and greater part of the night in removing his few belongings, piecemeal, to a friend's house at some distance from his own. This had to be done very warily, on account of the police, who, as he remarked, "might have asked questions." At 5 A.M., having completed this job, he knocked up a friend in order to bid him good-bye. This friend, knowing the man to be a "bit strange in his head," talked soothingly to him, and, having advised him "not to do anything foolish," regaled him with a cup of tea and a slice of bread-and-butter, and, on starting for his work at 5.45 A.M., left him asleep in a chair. Shortly after 6 A.M. the patient awakened and went back to his own house, where he finished his preparations by placing the bottle of poison on a chair, rolling up his coat to act as a cushion, and putting it against the wall close by, and writing his last instructions on a piece of paper which he pinned to his waistcoat. Then, seating himself on the floor so that he could lean against the coat, he "took the cork out of the bottle, put the neck well into his mouth, so as not to burn his lips, and took a good swig." He says he became unconscious almost immediately, but he evidently had time to re-cork the bottle and replace it on the chair, for there it was subsequently found. All this must have occurred at about 6.30 A.M., and the man was not discovered till 1.30 P.M. From inquiries made there is every reason to believe that the bottle originally contained three ounces of the acid, and afterwards there was found in it just short of two ounces. None of it had been spilled on the floor, chair, or on the patient's clothes. The fluid was of the colour of light port wine, quite clear, and of sp. gr. 1065; and I was assured by Dr. Stevenson of Guy's Hospital, who kindly examined it for me, that it consisted of the strong liquefied acid.

In this case it seems to be quite possible—nay, probable—that while the man was making his elaborate destructive preparations the stomach, by reflex action, was equally employed on a protective process—viz., pouring out a large supply of mucus, on which, when ingested, the acid chiefly acted. If this were not so, how can the thick, tenacious contents of the stomach be accounted for? Both the patient and his friend agreed that he had eaten only one slice of bread-and-butter in the morning, and the last food he had had before this was some bread twelve hours previously.

Surbiton.

THE MAGISTRACY (IRELAND).—On the recommendation of the Lord-Lieutenant of the county the Right Hon. the Lord Chancellor has appointed W. Langford Symes, Esq., L.R.C.P. &c., of Kiltegan, to the Commission of the Peace for the county of Wicklow.

A CASE OF STRANGULATED FEMORAL AND OBTURATOR HERNIÆ.

BY A. R. ANDERSON, F.R.C.S.,
SURGEON TO THE GENERAL HOSPITAL, NOTTINGHAM.

JANE S——, aged seventy-five, was admitted into the Nottingham General Hospital on Oct. 3rd, 1891, for a strangulated hernia in the left groin. She stated that for many years she had noticed a small lump, the size of a nut, in the groin, which had given her no trouble until two days before admission, when it had suddenly got much larger, and she thereupon began to complain of pain in the part, accompanied by vomiting and constipation. There had been no action of the bowels since the descent took place, but she said that she had been able to pass flatus. On examination of the left groin a lump the size of an orange was seen, which had evidently come through the saphenous opening. It was rounded in outline, firm, and very tender on manipulation. There was no impulse on coughing, and dulness on percussion. She was admitted at 6 P.M., and at 7.30 I saw her and operated, after failure of the taxis, under chloroform. On opening the sac a lump of omentum was found projecting through the saphenous opening, the neck of which was very tightly constricted at Gimbernat's ligament. This was notched, and the omentum drawn down and examined. It did not appear to be much damaged, and was reduced. No bowel was found. I then passed a finger through the inner ring and felt around it, satisfying myself that all was clear. The wound was closed with horsehair sutures and a dressing of mercurial wool applied. The operation lasted only a few minutes. The next morning (Oct. 4th) she had passed a fairly good night, and seemed decidedly better. She had been sick twice shortly after the operation, the vomited matter consisting simply of the contents of the stomach. I attributed the vomiting to the chloroform. An enema was then ordered, which was followed by an evacuation of fæces. On the following morning, however, she became rather suddenly worse and began rapidly to go down hill, unmistakable fæcal vomiting appeared, and on seeing her some hours later she presented the aspect of a person in the later stages of an unrelieved strangulated hernia. At this time she passed another motion. As it now appeared evident from the presence of these symptoms that there must be some unrelieved obstruction, I decided to explore further. Nothing could be discovered on examination of the groin, and being satisfied that there was nothing in the femoral canal, and failing to find a hernia elsewhere, I decided to open the abdomen. A median incision three inches and a half long was made in the linea alba below the umbilicus, and on introducing the hand I found that a knuckle of small intestine (ileum) had passed through the left obturator foramen and was there strangulated. The portion of bowel included was very tightly nipped by the sharp edge of the obturator membrane, beneath which the edge of a hernia knife was passed after considerable difficulty, and the membrane notched in a downward direction. The bowel was gangrenous, and gave way on being withdrawn. An examination of the parts outside the abdomen showed that the whole of the circumference of the bowel had not been included, and that the gangrene had involved a portion of the intestine, measuring two inches in length, but implicating only two-thirds of its circumference. A pair of Makins' clamps were at once applied, which effectually prevented any escape of the intestinal contents, the length of gangrenous bowel excised, and the divided ends joined together by means of Lembert sutures. On removal of the clamps the intestinal contents flowed freely past the line of suture and demonstrated its security. The abdominal wound was closed in the usual way. The patient, who was in a very unsatisfactory state at the time of the operation, did not rally, and died some hours afterwards. On a subsequent examination of the parts there was no leakage whatever from the sutured bowel, the opening in the obturator membrane admitted the forefinger, the femoral canal was empty, and there was nothing wrong with the lump of omentum which had been reduced. The obturator vessels and nerve passed through the foramen above and external to the sac.

This case appears to be worth recording on account of its clinical importance, as well as of the extreme rarity of the

Digitized by Google

simultaneous occurrence of these two herniæ, and a critical examination of the symptoms presented may be of interest. They were: sudden and great increase in size of a small irreducible hernia in the left groin, followed at once by pain in the part, vomiting, and constipation. 1. With respect to the swelling, this entirely disappeared after the reduction of the femoral epiplocele. At the time of the second operation the parts about the saphenous opening were carefully inspected, and no swelling of any kind existed at or about the situation in which an obturator hernia is known to protrude; indeed, as was afterwards shown, the knuckle of gut involved in the obturator foramen was too small to produce this sign. 2. The question as to whether the special pain existed along the course of the obturator nerve that is usually met with in these cases must remain doubtful. No inquiry was made as to such pain (the disease not being suspected), and no complaint was made of it. It is reasonable to suppose, however, that, if present, it was not severe, as she complained greatly on admission of pain referred to the region of the groin and nowhere else, and the morning after the first operation expressed herself as being free from pain. 3. With regard to the vomiting, no accurate information could be obtained about this symptom prior to admission beyond the fact that it had occurred, and the patient was not sick in the interval which elapsed between her admission into the hospital and the time of the first operation. It should also be noted that the vomiting which occurred twice after this operation, and which I attributed to the effects of the anæsthetic, was absolutely non-feculent in character, consisting simply of the contents of the stomach, feculent vomiting appearing suddenly on the second day after operation. 4. The constipation, it will be remembered, was not absolute. Although there had not been any movement of the bowels for forty-eight hours previous to admission, yet she had during that time passed flatus, and continued to do so on the day after operation. At this time her bowels were well moved after an enema, and there was another slight motion on the following day. All these anomalous symptoms, which made me doubt at the time that there was anything more than the severely constricted epiplocele to account for them, were probably caused by the fact that a portion of the calibre of the intestine had escaped strangulation and had allowed flatus and some liquid fæces to pass. Death resulted in this case from the inability of an aged and feeble person to bear the shock of the second operation; excepting for this, no reason was disclosed at the post-mortem examination why she should not have recovered. The fact that obturator herniæ usually occur in elderly persons, especially females, together with the difficulties in diagnosis, even when the case is not complicated, and the frequent delay in operating that consequently ensues, no doubt accounts for the very high mortality that has hitherto prevailed in such cases.

CHOREA FOLLOWING INFLUENZA IN A WOMAN AGED SIXTY-FIVE.

By P. A. McCARTHY, M.D., M.Ch., M.A.O. (R.U.I.), &c.

ON Jan. 26th I was called in to see Mrs. A. C——, aged sixty-five. She had been feeling unwell for some time previously, but had taken to bed only the day before. The usual symptoms of influenza were present, together with a slight cough. Temperature 101° F. In a few days the cough had gone and the temperature fallen to normal, but the prostration was very great and anorexia almost complete. It was with difficulty she could be persuaded to take nourishment of any kind; she "felt that she did not want it," and "everything had the same salty taste." She complained also of nausea and a burning pain in the pit of the stomach, and suffered a good deal from flatulence. To relieve these symptoms pepsine was given, effervescing draughts, ice, and mixtures containing soda, bismuth, hydrocyanic acid, &c., followed by quinine, strychnine, bark, dialysed iron, brandy, and champagne, but with very little benefit. For two weeks she continued in much the same condition, now showing slight improvement, again relapsing, but making no decided progress towards recovery. On Feb. 23rd choreic movements began in the fingers of the right hand, and three days later all the muscles of the arm and face had become involved. The arm was jerked about so violently that it was found necessary to secure it, the skin being broken in places. Her speech was much impaired, and she had to be fed from a feeding cup. Liquor arsenicalis was given, and she was put on milk, liquor carnis, peptonoids, peptonised cocoa and milk, brandy, and port wine. On the morning of March 6th the movements had entirely ceased, leaving the patient in a very exhausted condition, from which she never rallied; she grew gradually weaker, and died on March 11th. In her youth she had an attack of diphtheria, followed by paralysis of the right arm, lasting some months.

PHLEGMASIA DOLENS FOLLOWING INFLUENZA.

By C. ALEX. DUCKET, M.R.C.S.

ALTHOUGH phlegmasia dolens is a disease which occurs chiefly in the puerperal state, I have seen it lately in three cases of influenza, all of which bore striking resemblance to each other. Instead of the temperature going down, as is usual in an uncomplicated case, it kept up. There was great pain in the groin and upper part of the thigh, quickly followed by swelling, which extended over the whole limb. This rapidly increased, so that in two days the limb was twice as large as the non-affected one. The swelling was of a very solid nature, and did not pit upon pressure. There was not the least alteration by raising the leg. This state of things lasted for ten days, under the usual treatment, when the pain grew less, the limb softer, and the temperature fell to 99·8°. All three patients were affected in the left lower extremity, and were very restless. The obstructed vessels could be easily felt as hard cords. I may mention that the above patients were not subject to varicose veins, and, although married women with families, were never before troubled with their legs. The frequency of phlegmasia dolens in the lying-in period is attributed to the combination of slowness of the circulation with a varicose condition of the veins *plus* an extra amount of fibrin in the blood. May we not have exactly such a state of things during influenza?

Lavenham, Suffolk.

SOME CASES OF ABNORMAL SWEATING.

By L. FRAZER-NASH, L.R.C.P. & S.Ed.

CASE 1.—Amongst the patients who were attending the Hyderabad Dispensary in 1888 was a Hindu boy, upon whose skin was a crystalline deposit, more or less generally distributed, which suggested the idea that the boy had bathed in a saturated solution of some salt that had been allowed to dry on him. The crystals were glistening and amorphous to the naked eye, and required some friction to be removed dry. The family history was unimportant. The boy, who was ten years old, had suffered more or less since babyhood from malaria, and for four or five years his mother had noticed these white sweats, which, she said, occurred while he slept. I never found his skin other than dry, although he attended the dispensary for debility during some of the hottest months. The efflorescence was most marked on the legs, and notably over the shins; the crystals were also largely deposited on the back. About the head the crystals were coarser than elsewhere. The boy was thin, with flabby muscles, and his back was covered with rather long downy hair. The heart and lungs were apparently healthy. The urine, which I examined on one occasion only when the efflorescence was fully marked, was acid, sp. gr. 1008; no change on boiling. The microscope showed the usual phosphates. I tried to examine the skin deposit under the microscope, but failed to get more than epithelial scales and amorphous crystals. I regret to say I did not test the latter chemically, and, owing to press of work, was not able to take notes as fully as I could have wished. After a

Digitized by Google

course of tonics the white deposit on the skin became less and less marked, and in two or three months it had practically disappeared.

CASE 2.—This patient was sister to the above, a healthy child, about seven years of age. The deposit was well marked under her chin, and less so about her back. The mother said she always had it in the hot months.

CASE 3.—A Mohammedan boy aged thirteen had white efflorescence on his chest, back, forehead, and thighs. For two or three days he had had very slight bronchitis, and since then only had noticed the white sweats. I saw him only once or twice.

CASE 4.—A Mohammedan boy aged eight, suffering from sores on his abdomen, the result of contact with mango juice. Since he had had these abrasions only had the white sweats been noticed. The deposit was well marked on his face, chest, and back. He had no cough. I saw him only on that one occasion.

After this I noticed several cases at intervals, with a slightly marked efflorescence, generally in boys, always in natives. There was no irritation noticeable from the salts deposited on the skin, no sign of prickly heat or erythema. There was nothing abnormal about the quantity of urine passed. The food usually taken was milk, fruit, coarse bread, and water. The clothing worn is very slight, and a large surface of the body was exposed to the sun and air.

METROPOLITAN HOSPITAL.

CASE OF ENTERIC FEVER, WITH PULMONARY COMPLICATIONS, FOLLOWED BY LARYNGEAL DIPHTHERIA; TRACHEOTOMY; DEATH; NECROPSY.

(Under the care of Dr. HOWARD TOOTH.)

THERE are very good grounds for presuming that this is one of the rare cases in which a membranous or diphtheritic laryngitis complicates enteric fever. The aspect of the patient, character of the temperature chart, enlargement of the spleen, the papular exanthem and characteristic diarrhœa rendered the diagnosis of typhoid fever almost certain during life, while the ulceration in the cæcum and the enlargement of Peyer's patches and of the mesenteric glands (found post mortem) confirmed it. The diagnosis of diphtheria could not be made with certainty during life, though the albuminous urine and the enlargement of the glands in the neck, which came on after tracheotomy, rendered it probable. The membrane found post mortem was indistinguishable from that of diphtheritic laryngitis. For the notes of the case we are indebted to Mr. R. F. Standage, house physician.

T. T——, aged five, was admitted on Dec. 21st, 1891, with high fever and pain in the abdomen. For three days before admission he had been restless, had shivered, lost his appetite, and had been sleepless. There had been no diarrhœa. On admission his face was flushed, the skin hot and dry. Temperature 101·8°; pulse 120; respiration 20. There was slight tenderness in the right iliac fossa on gentle pressure. No tympanites. No spots on the abdomen. Spleen not palpable; dulness not increased. Tongue moist; furred down the centre, red at the tip and the edges. Heart and lungs normal.

Dec. 22nd.—Signs the same. Morning temperature 101·2°, normal in the evening. Has passed one rather light-coloured, formed motion. The patient is treated as a case of enteric fever; is on liquid diet. Quinine (two grains) and salol (five grains) powders thrice daily, and three minims of liquor sodæ chlorinatæ also three times a day.

23rd.—Gurgling and pain in right iliac fossa. Some papular rose-coloured spots on abdomen. Morning temperature 100°, evening 103·8°. Passed a liquid, light-coloured stool not containing any shreds or blood.

25th.—Morning temperature 101·4°, evening 104°. Sponging (tepid) ordered when the temperature reaches 104°. Pulse 132, regular, markedly dicrotic. Abdominal pain more marked. Spleen distinctly felt. No fresh spots. Passed two liquid "yellow-ochre" stools. Tongue furred in centre; moist. Breath of a sweetish offensive odour (? result of salol).

26th.—Morning temperature 103·2°, evening 103°; pulse 132 (dicrotic). Tenderness in epigastrium and right hypochondrium. Snoring rhonchi heard at both bases behind. Crepitant râles over the front of the chest.

28th.—Motions still loose and light coloured. No hæmorrhage. Rhonchi and bubbling and crackling râles over the whole of the chest. Heart sounds distinct. Morning temperature 101°, evening 105·4°.

29th.—Considerable diarrhœa. No hæmorrhage. Sick during the night. Delirious. Bronchial breathing at the right base behind. Respiration 40 (shallow). Urine: sp. gr. 1020, no albumen.

31st.—Spots on abdomen faded. Dulness at the base of the right lung behind. Loud bronchial breathing. The child continued in much the same condition till Jan. 4th, when the note says: "Better. Temperature 99·2°. Signs in chest improved. Less crackling and rhonchus."

Jan. 4th, 1892.—No bronchial breathing. Note impaired; not dull at right base.

5th.—Developed laryngeal cough, stridor, and aphonia.

7th.—Has been treated for laryngitis with a steam-kettle and tent; fomentations to the neck. Also, later, leeches were applied, but without improvement. During last night the stridor became very marked, cyanosis supervened, and there was marked recession of the chest walls. Urine: cloud of albumen. No membrane on the fauces. No enlargement of glands at the angle of the jaw. Air does not enter well at the bases of the lungs. 3 P.M.: Stridor and recession increased. Emetics administered. No improvement. 7.30 P.M.: Colour waxy pale. Very little air entering the lungs. 7.45 P.M: Tracheotomy performed below the isthmus. No membrane coughed or feathered up. Very little bleeding. Symptoms almost immediately relieved.

8th.—Slept well. Fed by nasal tube. Breathes easily. Coughs occasionally, but has not coughed up any membrane. Temperature 100·6°.

9th.—Troubled with cough in the night. No membrane brought up. Considerable swelling of glands in the neck. Urine albuminous.

10th.—Bad attack of dyspnœa at 6.30 A.M. Several small pieces of membrane removed by feathering, apparently from low down in the trachea. Pulse 160. 5 P.M.: Earthy colour. Pulse 180. 10 P.M.: Colour worse. Temperature 104°; pulse 180; respiration 68.

11th.—Tube left out at 10.45 A.M. Can breathe through larynx, but not completely. Patient got rapidly more collapsed, rallied in the evening, but, again collapsing, died at midnight.

At the post-mortem examination, made by Dr. C. F. Marshall, the larynx and trachea were found to be lined with diphtheritic membrane. No ulceration of the laryngeal mucous membrane, or necrosis of cartilages. The right lung was completely consolidated with old bronchopneumonia, the left being collapsed and somewhat congested. In the cæcum, close to the ileo-cæcal valve, was a congested Peyer's patch, slightly ulcerated at one spot. Several similarly congested Peyer's patches were found along the ileum, but none of them ulcerated. The mesenteric glands were enlarged, especially those in the mesentery attached to the cæcum. Spleen enlarged to about twice the natural size.

BRADFORD INFIRMARY, YORKS.

A CASE OF ACROMEGALY.

(Under the care of Mr. APPLEYARD.)

IN the following case some of the characteristic signs and symptoms of acromegaly, as described by M. Pierre Marie and others, are wanting. Of these the most noticeable is the absence of enlargement of the lower jaw and of the tongue, and of limitation of the fields of vision. But in nearly all other particulars the case appears to us to resemble very closely other cases of acromegaly. The accompanying engravings, taken from photographs, give a fair representation of this patient's appearance. For the

Digitized by Google

25th.—Morning temperature 101·4°, evening Sponging (tepid) ordered when the temperature 104°. Pulse 132, regular, markedly dicrotic. Abdo pain more marked. Spleen distinctly felt. Sm spots. Passed two liquid "yellow-ochre" stools furred in centre; moist. Breath of a sweetish odour (? result of salol).

26th.—Morning temperature 103·2°, evening 10 132 (dicrotic). Tenderness in epigastrium and hypo chondrium. Snoring rhonchi heard at both base Crepitant rales over the front of the chest.

27th.—Motions still loose and light colour haemorrhage. Rhonchi and bubbling and crackling over the whole of the chest. Heart sounds ob Morning temperature 101°, evening 103·4°.

28th.—Considerable diarrhœa. No haemorrhage during the night. Delirious. Bronchial breathing right base behind. Respiration 40 (shallow). Urine 1020, no albumen.

31st.—Spots on abdomen faded. Dulness at the right lung behind. Loud bronchial breathing child continued in much the same condition till when the note says: "Better. Temperature 98°. chest improved. Less crackling and rhonchus."

Jan. 4th, 1892.—No bronchial breathing. Note not dull at right base.

7th.—Developed laryngeal cough, stridor, and and tent; fomentations to the neck. Also, iced were applied, but without improvement. During the stridor became very marked, cyanosis supervened there was marked recession of the chest walls. cloud of albumen. No membrane on the fauces enlargement of glands at the angle of the jaw. not enter well at the bases of the lungs. 3 P.M. Note recession increased. Emetics administered. No ment. 7.30 P.M.: Colour waxy pale. Very laborious ing the lungs. 7.45 P.M.: Tracheotomy performed the isthmus. No membrane coughed or forced little bleeding. Symptoms almost immediately relieved.

8th.—Slept well. Fed by nasal tube. Breathing coughs occasionally, but has not coughed up any brane. Temperature 100·6°.

9th.—Troubled with cough in the night. Nothing brought up. Considerable swelling of glands in Urine albuminous.

10th.—Bad attack of dyspnœa at 6.30 A.M. small pieces of membrane removed by forceps from from low down in the trachea. Pulse 160. 5 colour. Pulse 180. 10 P.M.: Colour worse. Pulse 194; pulse 180; respiration 68.

11th.—Tube left out at 10.45 A.M. Can breathe larynx, but not completely. Patient got much collapsed, rallied in the evening, but again collapsed at midnight.

At the post-mortem examination, made by Dr. Marshall, the larynx and trachea were found to be with diphtheritic membrane. No ulceration laryngeal mucous membrane, or necrosis of cartilage. right lung was completely consolidated with acute pneumonia, the left being collapsed and somewhat congested. In the cæcum, close to the ileo-cæcal valve, Several similarly congested Peyer's patches were found along the ileum, but none of them ulcerated. mesenteric glands were enlarged, especially those mesentery attached to the cæcum. Spleen enlarged about twice the natural size.

BRADFORD INFIRMARY, YORKS.

A CASE OF ACROMEGALY.

(Under the care of Mr. APPLETON.)

In the following case some of the characteristic symptoms of acromegaly, as described by M. Pierre and others, are wanting. Of these the most striking is the absence of enlargement of the lower jaw or tongue, and of limitation of the fields of vision; nearly all other particulars the case appears to resemble very closely. The accompanying engravings, taken from photographs, represent two of this patient's appearance; notes of the case we are indebted to Dr. J. Lacy Firth, house surgeon.

H. L——, an unmarried weaver, aged forty-two, presented herself in the out-patient department of the Bradford Infirmary on Oct. 31st, 1891. She complained of pain in both ankles, rendering walking difficult, and of cessation of menstruation. She has had the pains in the ankles, which are of an aching character, for twelve months. They are always worse at the end of a day's work; so that, although she is able to walk to the mill in the morning, at night when her work is done she has to take the tram to her home, which is five minutes' walk distant. She ceased to menstruate twenty years ago, and during the whole of that period has only had catamenial discharge once—viz., ten or twelve years ago,—and on that occasion the discharge lasted only for one day and was inconsiderable in quantity. When menstruation ceased she began to suffer from severe headache. At first this was frontal. She had it almost every day. It was not associated with vomiting, and in all other ways she felt quite well at this time. The headache was always more severe at the menstrual epochs, and at those times she also felt heavy and drowsy. After the lapse of four or five years the headaches ceased to be frontal and became occipital, and about this time she became an out-patient at the Bradford Infirmary. She attended for twelve months, and the headaches gradually ceased, and she has not suffered from them since. At this time she had no abnormal sensations in the hands or feet, and she did not think anything of their size, which was less than at the present time. The patient first noticed the increase in size of her hands and feet about ten years ago. Her attention was drawn to the size of her feet because she was unable to obtain ready-made boots large enough to fit them, and since she has always had to get boots made to measure. About the same time she discovered that she could not obtain gloves large enough for her hands, and for this reason has not worn any since. Seven or eight years ago she gave up all sewing because she could not procure a thimble large enough. About this time also (seven or eight years ago) she suffered a good deal from pain in the right shoulder-blade, brought on by her work, and a little later the back began to grow out, and the curvature has gone on increasing since. The patient's face has been altering in appearance during this period. She thinks her nose has become larger and the lower lip, and has noticed the face becoming puffy and swollen. She has had a cough summer and winter for four years, and it has been specially severe the last two winters. Her appetite has been fair and never extraordinary. She has never passed more urine than natural. She has not been troubled with sweating, general or local. She has not suffered from cold extremities. For the last seven or eight years she has not cared to go out at all, because people "looked at her so." She has during the same period noticed alteration in her voice. She has difficulty in pronouncing her words distinctly. The patient never remembers being laid up with illness, excepting when she had measles as a child. Her mother is alive and healthy; her father died at the age of forty-seven in a decline. The patient has lost nine brothers and sisters. All died between three and four years of age, with the exception of one sister, who died of dropsy at thirty-one years of age. No relative was ever affected, to patient's knowledge, with large hands or feet.

Dec. 19th, 1891.—Patient is very pale and old looking. She is 5 ft. ½ in. in height. The conjunctivæ are very pale. She is thin, and the skin on the trunk and limbs is soft, supple, and loose, and there is very little subcutaneous fat, which is especially wanting on the limbs. The temperature varied from 98° to 98·4° F.; once or twice only it reached 99°. Head and face: The skin on the face is natural and fair, except on the nose, where it is coarse, the sebaceous glands being unduly conspicuous, and comedones present. The face is striking from the large size of the nose and the projection of the lower lip. The latter is large and loose, and hangs forwards and downwards. The dry mucous membrane of the lower lip is unduly conspicuous, and is of a ruby-red colour. The eyelids are markedly puffy in appearance, reminding one of Bright's disease, but there is no transparency of the swollen tissue, and it never alters. The face may be described as of rectangular form in the upper two-thirds, the lower third being triangular, owing to the shape of the chin, which is rather pointed. The nose is of large size; it measures from tip to forehead 2⅞ in., and from the cheek to the tip 2 in. There is asymmetry of the face, the nose having a deflection to the right side, the chin to the left. The forehead is wrinkled, and the naso-labial folds are marked. The cheeks are flabby. The circumference of the head at the level of the root of the nose and external occipital protuberance is 23⅝ in. The external ears are natural, with the exception, perhaps, that the tragus projects outwards more than usual. The zygomatic arches are rather conspicuous, and the malar bones. The right temporal region is somewhat bulged. The ocular conjunctiva is sallow. Arcus senilis is slightly marked. The tongue is but slightly, if at all, enlarged. The neck is short; it measures 13½ in. circumferentially in its middle. It is directed forwards. There is no enlargement of the thyroid gland. The thyroid and tracheal cartilages are easily felt, and show no enlargement. The hands are large. The fingers are of cylindrical shape and do not taper. The wrists are obviously enlarged. The circumference of the right hand at the knuckles is 9 in., of the left 8¾ in. The circumference of the forefinger at the second joint is 2⅝ in., at the proximal joint 3¼ in. The skin is very thin and loose, and free from fat on the dorsum of

FIG. 1.

the hand; thicker on the fingers behind. The skin of the palms is loose and thick, and on the ulnar border a mass of skin and subcutaneous tissue can be easily raised from and moved freely upon the subjacent metacarpal bone. When the hand is held straight out with the finger extended the terminal phalanges are invariably found to be slightly flexed. The patient can only fully extend the terminal joint of the left forefinger. She can over-extend the proximal phalangeal and the metacarpo-phalangeal joints. The nails are short and broad, and striated, especially those of the thumbs. The articular extremities of all the phalangeal bones are slightly larger than natural, and the joints are looser. The same remarks apply to the knuckles, and in the latter soft crackling is elicited when free passive movements are made. She can close the hands, bringing the fingers upon the palm fully and naturally. The lower ends of the radii feel large, and, to a less degree, the ulnæ. The skin of the palms is dry. The veins upon the back of the hands and in the lower parts of the forearms are noticeably enlarged. The olecranon processes are somewhat large, and also the condyles, and the latter are more easily felt than ordinarily, owing to the softness of the tissues around. The head of the humerus seems natural. There is a lipoma-like tumour, about the size of a hen's egg, between the spine of the scapula and the

Digitized by Google

clavicle on the left side. The clavicles upon inspection appear longer than natural; the length is 5½ in. from the sternal to the acromial articulations. Power of grasp in the hands is moderate. Sensation to touch and pain is perfect in the hands and forearms. Lower limbs: The feet are very large. Lying along the outer borders of the feet and upon the inferior and posterior surfaces of the os calcis there are pads of somewhat firm tissue. When the patient is standing this tissue is displaced outwards, and increases the breadth of the soles. The skin on the dorsa is thin and free from deposit. There is marked hallux-valgum in both feet, and the affected joints are larger than natural. There is a tendency to over-extension of the metatarso-phalangeal joints and to unnatural flexion of the distal phalangeal joints. The malleoli are natural and the upper extremities of the tibiæ and fibulæ seem natural in size. The patellæ seem large. The right one measures 3½ in. across its widest part and the left one 3¼ in. Owing to the softness of the muscles the condyles of the femora can be very easily felt. There is slight lipping of the edges of the trochlear and condylar articular surfaces; there is soft crepitus in the knees on movement. Patient is seen when standing to have genu varum. There is slight varicosity of the internal saphenous veins in the legs. The nails are transversely and longi-

FIG. 2.

tudinally striated. The feet are sometimes found bedewed with sweat, at other times dry. Back and chest: There is very marked kyphosis of the upper two-thirds of the dorsal region of the spine, and it is continued into the lower cervical region. There is slight lumbar lordosis and slight lateral curvature to the right in the upper two-thirds of the dorsal region. The right half of the back is very prominent. The shoulders are thrown forwards somewhat. The sternum is deflected to the right of the middle line. The ensiform cartilage is easily felt, and is perhaps rather longer than natural; it is not prominent. The second intercostal cartilages are very prominent, and especially so at the line of junction with the ribs. The costal cartilages are all prominent at the line of junction with the ribs. The ribs lie posterior in level to the cartilages at the junctions. The elevations formed as above are very similar to rickety beading. The girth of the chest is 34 in. at the level of the axillary folds. The heart sounds and apex beat are normal in character. Pulse 85 to 95, regular. The radial arteries are slightbly thickened, and the temporals just visible and slightly tortuous. Respiratory movement of the chest is deficient, and is rather of the nature of a jerk upwards than a true expansion. Percussion reveals hyper-resonance in front, except in the cardiac area, and behind normal resonance, except over the prominence of the right side. The breath sounds are harsh in both subclavicular regions and weak at the bases. There are sonorous rhonchi heard over both sides of the back and a few muffled râles at the bases. The patient's voice is thick and husky always, and monotonous. Abdomen and digestive system: The lower two-thirds of the abdomen are full and prominent, and marked off from the upper third by a transverse furrow, which crosses one inch above the level of the umbilicus. Resonance exists in all parts. No viscus palpable. Liver dulness exists in the sixth and seventh intercostal spaces in the nipple line. Patient's appetite is natural, and the bowels are regular. Genito-urinary system: The urine has been repeatedly examined, and in each instance was normal in character; its specific gravity varies between 1017 and 1020, the colour orange or amber, and it is clear. It yields no reaction with Fehling's solution, and contains no albumen. The quantity passed in the twenty four hours varied within the limits of eighteen and forty-two ounces, minimum and maximum, and was measured nearly every day for three weeks. The external genitalia are normal, and vaginal examination reveals a small cervix with nulliparous os and no abnormality. The distance between the anterior superior iliac spines is 10¼ in., and across the iliac crests, at the widest part, 13½ in. The patient is always in good spirits, and is of a contented disposition. The knee-jerks and plantar reflexes are normal. Her power of hearing is equally good on the two sides, but is much less than natural. She ceases to hear a watch at a distance of eight inches, which other persons hear at a distance of from two to three feet. Vision is unimpaired. There is no trace of optic neuritis. The fields of vision, tested with the finger, reveal no limitation. Perimeter not used.

MEDICAL SOCIETY OF LONDON.

Rapid Dilatation of Uterus for Hæmorrhage.

AN ordinary meeting was held on March 28th, Dr. De Havilland Hall, Vice-President, in the chair.

Dr. AMAND ROUTH read a paper on Rapid Dilatation of the Uterus for Diagnosis and Treatment in cases of Uterine Hæmorrhage. After discussing the preliminary treatment of cases of uterine hæmorrhage, the importance of exploratory dilatation of the uterus for those cases where no obvious cause existed was urged. Out of the fifty-two cases related, forty-two, or 81 per cent., were found to have a removable intra-uterine condition accounting for the hæmorrhage. As regarded Apostoli's treatment, he considered that, where permitted by the patient, and otherwise practicable, the cervix should be first dilated and the uterine cavity explored. The same proceeding should be also adopted before the alternative operation of oöphorectomy or hysterectomy was entertained, and it was shown that fourteen out of the sixteen fibroid uteri (88 per cent.) were found, after dilatation, to have a removable intra-uterine condition, such as polypus or fungous endometritis, as the immediate cause of the hæmorrhage. If a series of cases set apart for Apostoli's treatment could first have their uteri dilated, and be then tabulated according to whether the fibroids were intramural, submucous, or polypoid, or whether fungous endometritis were present, and the results recorded after the proposed treatment, the class of cases where electricity would do good would soon be known, and the previous dilatation would at the same time enable the operator to ascertain the spot were the current could be applied most advantageously. The details of the dilatation by long-handled metallic bougies were then given, rigid antisepsis being all essential. The fifty-two cases described consisted of 13 placental or membranous retentions, 5 polypi, 2 polypi and fungous endometritis, 2 fibroids without fungous endometritis, 7 fibroids with fungous endometritis, 5 granular endometritis, 5 malignant disease, and in 5 no intra-uterine cause was found. The following conclusions were considered to be proved:—1. That where there was profuse menorrhagia, and more especially where metrorrhagia was also present, without obvious cause, the cavity of the uterus should be explored. 2. That the best way to explore the uterine cavity was to rapidly

MEDICAL SOCIETY OF LONDON

Rapid Dilatation of Uterus for Hæmorrhage.

AN ordinary meeting was held on March 28th, Havilland Hall, Vice-President, in the chair.

DR. AMAND ROUTH read a paper on Rapid Dilatation of the Uterus for Diagnosis and Treatment in cases of Hæmorrhage. After discussing the preliminary treatment of cases of uterine hæmorrhage, the importance of which is generally recognised, he said that dilatation of the uterus for those cases in which no obvious cause existed was urged. Out of the 100 cases related, forty-two, or 81 per cent., were found to have a removable intra-uterine condition accounting for the hæmorrhage. As regarded Apostoli's treatment, he considered that, where permitted by the patient, curettage was practicable, the cervix should be first dilated and the uterine cavity explored. The same proceeding should be adopted before the alternative operations of hysterectomy or removal of the appendages were entertained, and in that fourteen out of the sixteen fibroids (87 per cent.) were found, after dilatation, to have a removable intra-uterine condition, such as polypus or endometritis, as the immediate cause of the hæmorrhage. If a series of cases were kept for a time, treatment could first have their uterine cavities explored, tabulated according to whether the fibroids were intra-mural, submucous, or polypoid, or whether hæmorrhagic metritis were present, and the results would be known. The proposed treatment, the class of cases which would do good would soon be known, and at the same time dilatation would at the same time enable the operator to ascertain the spot where the current could be most advantageously. The details of the dilatation, by handled metallic bougies were then given, the latter being all essential. The fifty-two cases consisted of 13 placental or membranous retention, 3 polypi, and fungous endometritis, 2 fibroids with fungous endometritis, 7 fibroids with fungous granular endometritis, 5 malignant disease, and 22 intra-uterine cause was found. The following were considered to be proved:—1. That after profuse menorrhagia, and more especially when metrhagia was also present, without abnormal pain, dilatation of the uterus should be explored, and before the uterine cavity was

dilated the cervix with graduated bougies under anæsthesia. 3. That with rigid antisepsis there was practically no risk, and very rarely any subsequent pyrexia, unless malignant disease or salpingitis were present. 4. That even where tubal disease was present or suspected, exploratory dilatation of the cervix, for metrorrhagia of apparently intra-uterine origin, was not necessarily contra-indicated, salpingitis being often secondary to and aggravated by intra-uterine disease. Here again antisepsis was all-important. 5. That where fibroids of the uterus were evidently present, the immediate cause of the hæmorrhage might be a removable one, such as a coexisting polypus or a fungous endometritis, and that therefore the uterine cavity should be, when practicable, explored, before removal of the appendages or hysterectomy was entertained. 6. That in some cases dilatation alone sufficed to greatly relieve both the hæmorrhage and the pain. 7. That if an exploratory dilatation were more often adopted prior to the employment of Apostoli's treatment, it would tend to a more exact knowledge of its applicability, and put its use on a more scientific basis.

Mr. DORAN said that the first thing to be satisfied of was the presence or absence of endometritis; but the precise nature of the latter affection was not quite known. The diseases of the tubes were fairly understood, as were also those of the ovaries, except cirrhosis, which latter seemed to correspond somewhat to baldness or whitening of the hair. The difficulty with the uterus was that there was something of its membrane cast from it every month, but precisely how much no one knew, and on that account it was very difficult to say what was morbid and what was not. The danger of endometritis was its extension to the tubes and peritoneum, and the great advantage of dilatation and diagnosis was that many diseases to which women were liable could be, by suitable treatment, thus nipped in the bud.

Mr. KNOWSLEY THORNTON agreed with the first and second of the author's conclusions, and he was also sure of the value of antisepsis. He never passed a sound but he followed it with a probe, on which was twisted a bit of cotton-wool dipped in iodine, and he left this in the uterus for a few seconds; he had not found pyrexia follow dilatation, even in malignant cases. He did not see why antiseptics were all important in pyo-salpinx cases, because in those it was quite impossible to protect the woman from sepsis. In many cases of uterine fibroid it was quite impossible to explore and to render the uterine cavity aseptic; it was far better to proceed with the major operation at once. He had found hæmorrhage and pain relieved by operation, sometimes in a way not easy to explain. He thought that a debate on this subject would prove useful to the profession at large, for there was still much ignorance on this subject, and he quoted, in conclusion, a case of fungous endometritis in which, for want of dilatation, carcinoma of the uterus had been diagnosed. Hysterectomy had been proposed, and, but for an independent opinion, would probably have been carried out.

Dr. HAYES agreed with the author's general conclusions, which accorded with his own experience. Long ago he came to the conclusion that dilatation by tents was dangerous, because it led to cellulitis and sepsis, and he had therefore adopted Hegar's bougies, which he had made with a more rounded extremity. He had found fixation of the uterus by vulsellum unnecessary, for where it was done it incommoded the further passage of bougies into the uterus. Before removing tumours he preferred, after rapid dilatation, to use a tent, as under the influence of the latter the uterus became softer. The only case in which he had met with accident in rapid dilatation was the following:—A woman past the climacteric was suffering from profuse and watery discharge. As he dilated, the uterus ruptured, both at the side and at the fundus, although no force was used. At the post-mortem examination there was found fatty degeneration of the liver and of the heart; the uterus itself was very soft, and apparently fatty also. He would hesitate to dilate if acute salpingitis were present.

Dr. WILLIAM DUNCAN thought that in all cases rapid dilatation should be resorted to in preference to gradual, there being far greater risk with the latter. The only exception he would make would be in the case of malignant disease of the fundus. He held that the uterus should be fixed with a vulsellum, as a case had been recorded in which the organ had been torn from its connexions where dilators alone had been used. Where the cervix could not be easily gripped he usually made a small bilateral slit and then passed one blade inside the cervix and one out. In fibroids the operation of hysterectomy or of removal of the appendix should be preceded by dilatation of the cervix. He related two cases in which, having neglected to previously dilate the cervix, he removed the appendages for fibroid, without checking the bleeding. One of the patients subsequently returned. He then on dilatation found a pedunculated fibroid as large as an orange, which he removed with the écraseur, with the result that the hæmorrhage almost entirely stopped, though some intra-mural fibroids still remained. Slight lacerations of the cervix were of no moment and healed up rapidly; they were obviated in the virgin uterus by lateral incision. He had found that dilatation could be carried out without the aid of an anæsthetic in many cases in multiparæ. He agreed cordially in the advantage of thorough asepsis. After dilating he introduced iodised phenol and placed an iodoform bougie in the canal, which was kept in place with a plug of glycerine.

Dr. JOHN WILLIAMS did not know why Hegar's dilators were considered to be so good, and why tents were so depreciated. The latter had, till comparatively lately, been constantly used with very few bad results, if the patients were kept in bed and on their backs. Rapid dilatation by bougies was better when pregnancy had recently occurred, but in women who had not been pregnant for a long time the risk was very great. To dilate a uterus so that the forefinger could be introduced as far as the fundus meant that the cervix must be lacerated in every case, and the tear began at the internal orifice and extended downwards; therefore he could not see why incising the external os should stop it. Such a laceration would leave a scar which might give rise to trouble afterwards. It was not necessary to dilate a uterus for diagnosis so that a forefinger could be passed into it—endometritis, for instance, could be easily told by the way in which a sound passed gently over the surface of the mucous membrane produced hæmorrhage. For the treatment of that condition rapid dilatation was most valuable, the canal being dilated up to the size of a No. 18 English, and the curette then being freely used. In cases of hæmorrhage the cavity of the uterus should not be explored until the case had failed to be controlled by medicine. The risk of rapid dilatation was slight, but in one case, about six days afterwards, what appeared to be a hæmatocele developed, but the patient did quite well. He had dilated safely in instances in which there were lateral swellings on each side of the uterus. If hæmorrhage were present in association with tubal disease, its occurrence was probably accidental. He admitted the advantage of dilating in many cases of fibroids; at any rate, if this were done more frequently, a large number of women might have their ovaries saved.

Dr. HEYWOOD SMITH agreed that in many cases it was not necessary to go beyond a No. 18 in dilating, and the operator himself should certainly hold the uterus in order to estimate the amount of resistance. He advocated the employment of Bell's dredge curette, which he held to be more efficient than most in use. Any plugging that was necessary should be accomplished by means of gauze in strips. He referred to a case of pyo-salpinx in which the whole tubeful of pus emptied itself into the uterus during the catamenial discharge, and perhaps dilating and curetting in these cases might be of value in promoting this.

Dr. HORROCKS said that from a consideration of the structure of the cervix he could not see how laceration could be avoided in rapid dilatation. Tents did not lacerate to the same extent, because the process was a more physiological one. He had never had any serious results from the use of the bougies, though at Guy's Hospital a Hegar's dilator had been pushed through the uterus into the peritoneal cavity without untoward result. The patient died four months later of another lesion, and the scar in the uterus was then distinctly visible. He held that there were cases in which dilatation of any kind was injudicious, and in others, such as those in which the patient had not been pregnant for a considerable time, it was better to use laminaria tents which had been soaking in absolute alcohol containing corroive sublimate.

Dr. CHAMPNEYS said that he thought that too much had been made of the idea that Hegar's method was the only antiseptic one. It could never be certain that the cases were aseptic to start with, and either a bougie or a tent might bring in septic pus with it. With care a laminaria tent could be made not only harmless of itself, but it could be used as the vehicle for the introduction of a certain amount

Digitized by Google

of powerful antiseptic to the benefit of the patient. A tent not well prepared might become foul, but if carefully applied and the vagina well packed with antiseptic behind it, it could be kept sweet for hours or even days. Hegar's method was especially useful where the cervix was moist with secretion, for it was then in such a temper as to yield readily. The cases of rigid dry cervix should be prepared with a tent before using the bougies.

Dr. LEWERS said that reference had been made to his paper on Rapid Dilatation of the Cervix read before the Harveian Society some five years ago. Many then present who were opposed to the method had since become strong supporters of it. He himself now considered that rapid dilatation was not a method to be universally applied in all cases, but that it was of special value where dilatation was required at no long time after a confinement or miscarriage, or in cases of molar pregnancy. For such cases it was a perfect method. On the other hand, in cases altogether apart from pregnancy, or in those who had never been pregnant, rapid dilatation often meant laceration, and for such cases dilatation by means of laminaria tents, rendered aseptic and antiseptic by prolonged immersion in a 1 per cent. solution of corrosive sublimate in absolute alcohol, was the best method.

Dr. AMAND ROUTH briefly replied, remarking that he did not consider it safe to hurry too rapidly over the smaller sizes at the beginning of the process. He agreed that most cases could be diagnosed when the size of No. 15 Hegar was reached, and he only dilated further if operative measures had to be adopted.

CLINICAL SOCIETY OF LONDON.

Compound Ganglion of Wrist.—Thiersch's Method of Skin Grafting.—Leucocythæmia.—Unusual Cutaneous Eruption. — Transposition of Viscera. — Thyrotomy for Malignant Disease of Larynx.—Peculiar Lesion of Soft Palate.—Congenital Malformation of Thyroid Cartilage.—Cardiac Asthenia following Influenza.—A Renal Affection resembling Raynaud's Disease.

A CLINICAL MEETING of this Society took place on March 25th, Mr. H. G. Howse, Vice-President, in the chair.

Mr. STANLEY BOYD showed a man aged fifty-two, who had been affected with Tubercular Arthritis of the Wrist and Compound Ganglion, the latter being secondary to the former. The wrist was excised and the ganglion laid open, the tendons, so far as they were affected, being thoroughly scraped. A very good recovery had resulted, though the muscles of the thenar eminence had become wasted. There was found to be an enlargement of the median nerve, which, though it abutted on the ganglion, was independent of it.

Mr. FREDERIC EVE and Mr. J. A. LAWRENCE showed two cases, a woman and a man, who had been the subjects of Rodent Ulcer extending over the bridge of the nose. The growths were freely removed, and the surface left cleansed with a 1 in 2000 mercuric chloride solution, the mercury being washed away with sterilised salt solution. The surface of the skin used for grafting was similarly cleansed, and the raw surfaces completely covered. The grafts had taken, and the patients were shown with the surfaces covered with healthy skin.

Dr. ORD exhibited two cases of Leucocythæmia. The first occurred in an Italian aged thirty-six, who presented no history of malarial disease. He had had rheumatic fever some time previously. Six months before admission the abdomen commenced to increase in size, due to enlargement of the spleen. Later, anasarca and ascites developed. There was no febrility; and the urine contained one-third of albumen, with free blood and epithelium and with hyaline and epithelial casts. The blood showed a large increase of white corpuscles with a diminution of red discs and of hæmoglobin. There were feathery hæmorrhages into the retinæ. He was treated at first for dropsy, which disappeared, and then was given arsenic, under which the spleen diminished rapidly in size, the urine contained hardly a trace of albumen, and the blood was normal. The second case was that of a schoolmaster aged forty, who eight months ago noticed swelling of the abdomen, and four days before admission was attacked with severe and painful diarrhœa. On examination there was a very large spleen; the blood was loaded with leucocytes, which, as in the previous case, were large, granular, and showed but little amœboid movement. The diarrhœa was controlled by bismuth and opium, and then under arsenic the spleen diminished rapidly. He thought that the fluctuations under treatment were larger than usual in leucocythæmia, and in both cases he considered the rapid improvement due to removal of causes of irritation, rather than to cure by drugs in the ordinary way.

Dr. ORD likewise introduced a man aged twenty-nine who presented an unusual Eruption on his Chest. It much resembled acne in appearance, there being red elevations and comedones. It ran round the body in a band, but differed from herpes in that it did not follow the course of the nerves. There was no history of the application of a plaster.

Dr. ARTHUR DAVIES showed a boy eight years of age with complete Transposition of Viscera associated with morbus cœruleus.

Dr. SEMON first showed a case in which he had performed thyrotomy for Malignant Growth of the Left Ventricular Band and Ventricle of Morgagni, in a gentleman aged thirty-eight, on June 2nd of last year. The growth was a squamous-celled carcinoma. The patient had recovered without any incident whatsoever. There was no trace of recurrence, and the result was excellent so far as phonation was concerned. Although all the soft parts on the left side of the larynx, including the left vocal cord, had been removed, the patient's voice was practically normal. The situation of the former growth was occupied by a smooth cicatrix, with a prominent ridge corresponding to where the left vocal cord had been, and the right vocal cord on phonation to some extent crossed the middle line and almost touched this ridge.

Dr. SEMON next exhibited a case of an Obscure Affection of the Soft Palate. The patient was a married woman aged twenty-two, who complained of soreness in the throat and swelling of the glands since August last. The affection began with a cold, followed by swelling of the gums, and when this subsided the throat became bad, and the glands in the neck swelled. The tongue had never been affected. She married two years ago; her husband was consumptive, and came from a consumptive family. She had had no children, and no miscarriage. There was a good deal of dysmenorrhœa, but there was no history and no other evidence of syphilitic disease. On examination of the throat when the patient first came to the hospital it looked very much like a case of commencing tuberculosis of the palate, and local treatment by lactic acid was therefore commenced, but without success. The disease, on the contrary, spread over almost the whole of the soft palate, and in parts came to resemble the margins of the condylomata of secondary syphilis. Energetic specific treatment had been resorted to, but neither various mercurial preparations nor iodide of potassium had had the slightest influence upon it. The infiltrated part was very tender to the touch, as were also the considerably enlarged cervical lymphatics underneath the angles of the jaw on both sides. The case was brought forward for suggestions as to diagnosis and treatment. The opinion had been expressed that the disease of the palate was analogous to the so-called "geographical tongue"; but, apart from the fact that he knew of no such affection ever having been observed on the palate, the intensity of the pain, the occurrence of actual ulceration, and the swelling of the glands seemed to differentiate it even clinically from that affection. He himself inclined to the belief that it was of a parasitic nature. He intended to examine scrapings both microscopically and bacteriologically. For comparison's sake a genuine case of tuberculosis of the palate, occurring in a woman of about the same age, was shown which had already been considerably benefited by scraping and local applications of lactic acid.

Dr. SEMON lastly exhibited a case of Congenital Malformation of the Larynx and Trachea, with a Diverticulum of the Œsophagus. The patient, a single woman aged twenty-six, came to the throat department of St. Thomas's Hospital in the beginning of this year, complaining of "thickness in the throat" and occasional regurgitation of undigested food an hour or more after meals. The pharynx and œsophagus, so far as visible, were perfectly normal, and bougies were passed easily into the stomach without encountering any obstacle. The thyroid cartilage was more prominent than usual and the larynx seemed to stand much lower in the neck than under normal circumstances. The

Digitized by Google

two halves of the thyroid were not united in front by firm cartilage, but merely by a thin ligamentous connexion, and the finger-nail could be easily introduced into the fissure thus resulting. The right half of the thyroid also distinctly overlapped the left one. Laryngoscopically, the right half of the larynx was seen to stand somewhat higher than the left, and one could look right down into the right ventricle of Morgagni, the right vocal cord being visible along its entire breadth. The cords moved well in respiration and completely touched one another in phonation. There was, in addition, an apparent displacement of the trachea, for which, on examination of the neck and chest, no explanation could be found. As to the œsophageal affection, the probabilities were in favour of a diverticulum. There was no family history of congenital malformation.

Dr. BURNEY YEO read a paper on Cardiac Asthenia following Influenza. The author called attention to the frequency with which cases of notable cardiac asthenia had been observed to follow attacks of epidemic influenza. The circumstances under which these cases occurred and the symptoms which characterised them were then detailed. Two instances of aortic regurgitant murmurs developing after influenza attacks were briefly quoted, and the author then gave the details of a more remarkable case which had been under his care in King's College Hospital. A dark-looking well-built man aged thirty-eight, an oil presser, had always had good health until suddenly attacked with dyspnœa and palpitation about three months before admission. His chief symptoms were very great irregularity of pulse and heart beat, anasarca of the lower extremities, albuminuria (which completely disappeared after two or three days' rest in bed), great enlargement of the liver, a large effusion into the right and a smaller effusion into the left pleura. Notwithstanding all this the patient's general condition was good. He had no pain, no fever, no rise of temperature, his tongue was perfectly clean, his appetite good, his bowels regular, his head clear. A careful clinical analysis of his symptoms traced them all to a rapidly produced acute cardiac asthenia with dilatation. There was no evidence of any valvular disease. The rarity of such a condition was pointed out, and it was urged that the only possible way of accounting for it must be the preceding occurrence of some infective disease, the original symptoms of which were so slight and casual as to escape observation. Such a disease we had had in the recent influenza epidemic. On further scrutiny into his previous history it was ascertained that during the epidemic of last spring he had been laid up for three days with pain in his back, but he had paid very little attention to the attack. Different views as to the nature of these cases of post-grippal cardiac asthenia were referred to, and the possibility of their origination in sclerosing arteritis of the coronary vessels, the result of bacillary influenza, was mentioned. Some observations by Huchard and his views on this subject were referred to, especially as to the dependence of these phenomena on lesions of innervation. Some remarks on the most appropriate treatment of these cases concluded the paper.—Dr. FRANCIS TAYLEUR said that no doubt the heart was affected in a peculiar manner by the poison. In the post-febrile condition he had seen the pulse reduced to 50 or lower, and he quoted a case in illustration of this. The fact that they recovered pointed strongly to the neurotic causation of this condition.—Dr. LONGHURST inquired of the author what his views were as to the exhibition of alcoholic stimulants.—Dr. GOODMAN had observed extreme pulsation of the abdominal aorta as a result of influenza. It was associated with marked exaggeration of the aortic second sound, and no change of pulse.—Dr. PERCY WIGHTWICK asked what was the prognosis in these cases. He had met with marked acceleration of pulse in a man of seventy, who bore digitalis badly; his pulse did not return to the normal till six months afterwards.—Dr. YEO, in reply, said he was averse to excessive alcoholic stimulation in these cases. He had found that a grain each of quinine and phenacetin every hour had proved useful in a case associated with hyperpyrexia. The prognosis was good if a proper period of rest were secured to the patient, but this he believed in some cases required to be measured by years rather than by weeks or months.

Mr. HOWARD MARSH read notes of a case in which an affection of the kidney presented points of resemblance to the phenomena observed in Raynaud's disease. The patient, an unmarried woman aged twenty-five, was originally admitted into St. Bartholomew's Hospital in June, 1886, with symptoms of a stone in the left kidney. There were all the usual symptoms of renal calculus, and the urine contained pus and blood. He cut down upon the kidney to explore, making the incision in the mid-axillary line in order to gain more room. He found nothing, and as the symptoms continued, he subsequently cut down in the middle line of the abdomen. He then discovered that it was freely mobile, and was withdrawn out of reach when the deeper parts of the wound were retracted. No stone, however, was found, but as the kidney was atrophied and useless, it was removed. The patient made a good recovery, and was discharged in September, 1886. After removal the kidney was found to contain three small calculi. It was remarkable that the kidney should have undergone atrophy on this account, for the size of the calculi was such that they might have passed without difficulty. A month later the patient was readmitted with pain in the right kidney. There was typical renal colic, with almost total suppression of urine. In January the right kidney was explored, but nothing was found. The symptoms, however, subsided, and the patient went on well until the following December. During this time, however, she had occasional attacks, and on Jan. 29th she was admitted again after an attack of unusual severity. For some days after this she had partial suppression of urine and occasional attacks of severe suffering, and these recurred at intervals until July, when the kidney was again exposed by an incision through the right linea semilunaris. The kidney seemed healthy and moderately hypertrophied. No dilatation of the ureter. Matters then went on as before, with occasional attacks, until in February, 1888, the kidney was again explored, the ureter was opened two inches below the pelvis of the kidney, and a long probe passed down it. No obstruction, however, was found. The substance of the kidney was then incised so that the pelvis and calyces could be explored with the finger, but still nothing was found. The patient gradually sank, and died on the 17th. At the necropsy an opening was found in the cæcum due to ulceration of the vermiform appendix. The right ureter was a little dilated and bound down by fibrous bands to the cæcum. The mischief in the appendix had probably occurred in the previous November, when there were symptoms of appendicitis. The author discussed the symptoms: he pointed out that the condition of the left kidney seemed to account for the symptoms on that side, but on the right side there was no mechanical condition to account for them; and the symptoms were presumably due to some profound vasomotor disturbance similar to that associated with Raynaud's disease. He pointed out that Raynaud's disease was by no means constantly symmetrical nor confined to distal parts, such as the fingers and toes; but might, on the contrary, affect various districts of the circulation. At the same time the author was not prepared to assert that this case had the same pathology as Raynaud's disease. He insisted only on the fact that the symptoms were those usually taken to indicate calculus with obstruction, but the case evidently belonged to a group of cases in which severe paroxysmal pain and various symptoms referable to the kidney might be present, but of which no adequate explanation could be given.

Mr. MANSELL MOULLIN referred to a case, particulars of which he had communicated to the Society earlier in the session. He desired help in the differential diagnosis of the colic of renal calculus from other forms of renal colic not associated with stone.

Reviews and Notices of Books.

Traité de l'Hygiène Publique, d'après ses Applications en France, Angleterre, Belgique, Allemagne, Autriche, Suède, et Finlande. PAR DR. ALBERT PALMBERG, President de la Société d'Hygiène de Finlande. Translated from the Swedish into French by M. A. HAMON. Paris: Octave Doin. 1891.

THAT the preservation of public health is an international question is forcibly illustrated by the admirable and comprehensive work which Dr. Palmberg has already published in two languages. No greater mistake could be committed than to believe that the nations which have made the most progress in sanitation have nothing to learn from countries which are in the rear rather

than in the van of progress. In every country some good points may be found, and this truth is rendered evident by even a mere glance at Dr. Palmberg's studious record. Thus, in spite of the vaunted sanitation of England, and though we are acknowledged to have led the way in modern sanitary reform, it is in the united kingdoms of Norway and Sweden that the lowest death-rate has been secured. This was only 17·2 per 1000 compared with 19·0 per 1000 for England during the year 1887, 20·5 for Belgium, 21·0 for Finland in 1888, 22·0 for France in 1887, 26·6 for Germany during the same year, 29·4 for Austria in 1888, and 34·6 for St. Petersburg in 1888. Dr. Palmberg attributes the low death-rate of Norway and Sweden as much to the high degree of civilisation and the morality of the people as to the excellence of their hygienic laws and institutions. The sanitary laws of Sweden comprise, among other rigorous enactments, measures for the construction of isolation hospitals, the compulsory removal of patients suffering from infectious diseases to these hospitals (unless they possess sufficient means of isolating themselves), and the obligatory disinfection of rooms, furniture, and wearing apparel. Vaccination has been enforced in Sweden since 1853, and the law insists that all towns shall have a good supply of pure drinking water. But we cannot here analyse the sanitary legislation of Sweden, and have only mentioned one or two points to show that this country is well abreast of other nations. England occupies the first and largest portion of the book. There is a chapter on our sanitary administration, two lengthy chapters on our sanitary legislation, and then we have two chapters on London. After this there are chapters on Scotch sanitary legislation and on Edinburgh. But Dr. Palmberg not only deals with the laws; he also gives very full descriptions of the practice of hygiene. With the aid of more than two hundred illustrations he describes the notable inventions, the methods of draining, of ventilating, and of warming, which in each country seemed to him most remarkable. We have therefore before us a very useful book of reference, that will render great service to every international sanitary reformer. There are seven chapters devoted to Great Britain, three to Belgium, three to France, and three to Germany; Austria, Sweden, and Finland have two chapters each. But the information given is all arranged on the same principle: first the law, then the practical application of the law, and finally an account of ingenious inventions, devices, and contrivances for the maintenance or improvement of sanitary conditions. Thus, for instance, we have drawings of the different disinfecting stoves, portable and fixed, used in various countries, with accompanying letterpress descriptions. The methods of house drainage employed in each country are similarly illustrated. While thus giving a vast amount of useful information, Dr. Palmberg is very reserved in the expression of any opinion. He is nevertheless loud in his praise of England, which, he declares, possesses the most complete and precise sanitary code in the civilised world. On all sides the "marvellous effect" produced by these good laws may be observed. France, on the other hand, meets with but a small measure of praise. Since the great revolutionary epoch, since the laws of Nov. 14th, 1789, Aug. 16th and 24th, 1790, and Sept. 28th, 1791, little or nothing has been done in France by the Legislature. Dr. Palmberg might have added that, instead of progress, these laws, which are now a century old, have been to some extent rendered inoperative by the more modern and very injurious law of April 13th, 1850. These same laws, with the exception of the latter, still govern Belgium, where they were imported by the French Republican armies. They give to each commune very extensive powers; and it is by the use of this local autonomy that Brussels has become a model town in Europe. But in France these powers are curtailed by the much-abused law of April, 1850. Dr. Brouardel, the dean of the Paris Faculty of Medicine, in a gracefully written preface, introduces the French translation of Dr. Palmberg's book, and notices that the author is somewhat severe in respect to the backwardness of French sanitary legislation. But Dr. Brouardel acknowledges the truth of the criticism, urging, however, that it is no use making laws before public opinion is ripe for them, and then compliments the English on the practical sense they have shown in sacrificing the privileges of individual liberty for the preservation of public health. In conclusion, it should be observed that Dr. Palmberg has attended all the more recent international congresses of hygiene, and the volume he has produced is a striking proof of the great utility of such gatherings.

Saturn's Kingdom; or, Fable and Fact. By CHARLES MOORE JESSOP. London: Kegan Paul and Co. 1891.

THIS book is rather a collection of essays than a continuous work, though it commences with the consideration of such broad subjects as time and distance, the solar system, and the early history of the world, continues with the history of the development of life and the phylogeny of man, and ends with a discussion on primitive religion. Mr. Jessop (who, by the way, is a member of the medical profession) has collected a large number of interesting facts, which he has arranged under separate headings. Thus, speaking of distance, he quotes the astronomer Herschel, to the effect that the sun advances through space with a velocity of 154 million miles per annum. But, he says, the seven figures which represent one million convey to the mind no idea of the magnitude of one million. But if we take a tape, as suggested by Mr. Croll, of 83 ft. 4 in. long and divide it into tenths of an inch, each tenth representing one hundred years, this tape extended will convey some idea of the enormous amount expressed by the word million. Mr. Nasmyth's method of bringing home to the mind the same number is also ingenious. For he shows that sixty columns of the ordinary type of *The Times* newspaper represents about one million letters. Mr. Jessop states that he recently constructed such a sheet, and that, oddly enough, when the sheet was completed, there was a blank space of about twelve inches at the end of a column, which would correspond very nearly with the amount of type required to express the age of the world as ascertained from history. A chapter is devoted to the subject of the sun's heat, and the author endeavours to show that the radiant energy of the sun is not derived from combustion, since that could only last for a brief period; nor from the falling of meteorites upon the surface of the sun, though it can be proved by calculation that the weight of 1 lb. on the earth is equal to 28 lb. on the sun's surface, and as the sun's radius is 426,292 miles, the energy of 1 lb. of matter falling into the sun from infinite space would equal that of a 28 lb. weight descending upon earth from 426,292 miles: supposing the force of gravity to be as great at that elevation as it is at the earth's surface, it would amount to upwards of 63,000,000 foot-pounds. But even this would not be a sufficient source for the continuous heat radiated from the sun. There is, however, another theory of the origin of the sun's heat, that, namely, of the contraction of its mass, and by calculation it appears that with the present magnitude of the sun its whole diameter need contract but 220 feet per annum to produce all the heat it now radiates. This contraction will amount to four miles in a century. It is not impossible that the heat of the sun may be the result of the collision and fusion of two bodies moving in space towards each other at the speed of 476 miles per second, which is not beyond that of other stellar bodies. In such case the heat promptly generated would equal fifty million years of the present intensity. In a similar interesting though speculative manner he dis-

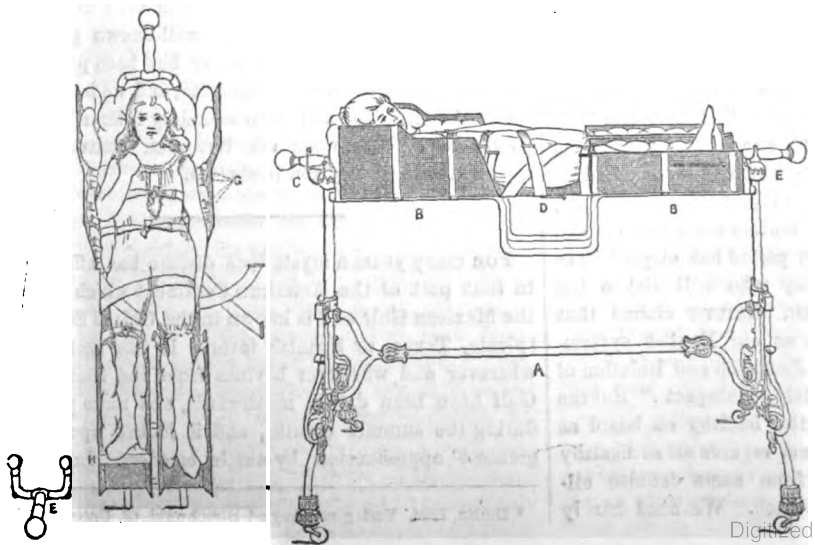
cusses the age of the habitable earth from the thickness of the sedimentary rocks, the denudation from rain and rivers, and other data. The Falls of Niagara, estimating their recession at one yard in one year, have existed 12,000 years. The inundation of the Nile raises the land of Egypt four inches and a half in a century. Interesting chapters are devoted to the antiquity of man, the gradual development of the faculties, and primitive religion. Some of the author's statements seem to us to be open to discussion. Thus, in one place he remarks that in man sight is not impeded by a long muzzle, *therefore* (the italics are ours) the sense of smell is unnecessary to sight. Is not this a *non sequitur?* Again, Mr. Jessop remarks that up to 1900 years ago a considerable section of the Hebrews did not believe in the immortality of the soul. Hence, the idea of a soul living for ever is a notion of yesterday compared with the duration of man upon earth. Again, we think a *non sequitur*. Other nations may, and probably did, hold the doctrine of the immortality of the soul. There is much else that deserves perusal, and we can recommend Mr. Jessop's book as one which may well prove a welcome companion after a hard day's work.

A Practical Guide to Meat Inspection. By Thomas Walley, M.R.C.V.S. Second Edition, Revised and Enlarged, with Forty-seven Coloured Illustrations. Edinburgh and London: Young J. Pentland. 1891.

That a second edition of Professor Walley's "Practical Guide to Meat Inspection" has been called for so soon after the appearance of the first is ample evidence that such a work was needed. There can be no doubt that the publication of the first edition opened the eyes, not only of medical officers of health and market inspectors, but also to some extent of the general public, to the importance of this subject. We are still far behind continental authorities in this matter, and, as an example of this, Professor Walley points to the meagre staff of any of our large abattoirs as compared with those of a place like Berlin, where at the central abattoir no fewer than 250 persons, including a director, nineteen veterinary surgeons, and six assistant veterinary surgeons, are engaged in inspecting, classifying, and stamping the meat from carcases slaughtered there; whilst about fifteen veterinary surgeons are engaged in the inspection of carcases slaughtered elsewhere, and brought into the city.



Professor Walley takes up in order the following questions:—The substitution of the flesh of animals not generally used for human food for the flesh of those so used; marketable and unmarketable flesh; rules to be observed in the inspection of meat; examination of the carcase for the purpose of detecting abnormal conditions, such as those due to violence or disease. He then takes up *seriatim* the various diseases that may cause changes in the meat, giving prominence to the cachectic conditions, diseases due to animal parasites and those due to vegetable parasites, and amongst these latter especially to tuberculosis. The work finishes with a chapter on refrigeration, frozen, salted, preserved, and tinned meats and fish, in connexion with the latter of which he is strongly of the opinion that "all fish in which evidence of putrefactive change exists should be unhesitatingly condemned for the purposes of human food." The chapter on legislation in reference to the consumption of animal flesh, fish, &c., will be useful to medical officers of health. The illustrations, coloured and uncoloured, at the end of the work should prove valuable to those who have to study this question of meat inspection; they are taken from actual specimens, and may therefore be used for comparison with specimens that come under observation. In this edition many corrections, additions, and improvements have been made. The book well illustrates the results of the work of a practical man of wide experience carried out in a thoroughly scientific fashion.

New Inventions.

NEW FEEDING CUP.

Miss Mina Forrest, nursing sister at the Herbert Hospital, Woolwich, has submitted to us a specimen of a new feeding cup which she has designed, and for which she claims the following advantages:—(1) The initial cost is trifling; (2) being made of bright metal it is practically unbreakable; (3) the mouth-piece, which is removable, is easily cleaned and kept sweet; (4) the cup, being furnished with a hinged lid, is capable of being completely covered, and the contents thus preserved from dust and other atmospheric impurities; (5) the interior of the vessel being graduated, the exact quantity of nourishment given can be accurately measured; (6) the handles, of which there are three—one at each side and a third at the back—are conveniently placed for holding by either patient or nurse. The cup, which is manufactured by Messrs. Evans and Wormull, is likely to be as useful as it is certainly elegant.

BEDSTEAD FOR USE IN HIP DISEASE.

Our attention has been directed to the difficulty likely to be felt by some of our readers in the endeavour to gain, by a mere verbal description, a clear conception of the nature of the apparatus mentioned by Mr. Stanmore Bishop in his paper on Morbus Coxæ published in our columns on March 12th. We therefore supply a pictorial representation of the cradle designed for use in such cases, and which, as already stated, is manufactured by Mr. John Carter of New Cavendish-street, London, W.

THE LANCET.

LONDON: SATURDAY, APRIL 2, 1892.

IN his presidential address to the British Guiana branch of the British Medical Association, Dr. ROBERT GRIEVE, well known in England in connexion with the office he formerly held under the Metropolitan Asylums Board, dealt with the question of quarantine, and the burden of his paper was to show grounds why he differed from our English views in so far as their application to his colony is concerned. For reasons which we will refer to we see no ground for dissenting from him on this point. But there are one or two passages in the address which need some comment. He says that after careful search he has failed to discover what the quarantine is to which so much objection is taken by English writers, and he adds: "Isolation and disinfection, as ordinary sanitary precautions, are admissible; but call them by the name of quarantine and they thereupon change their character and become something to be reprobated by all laying claim to be fully civilised." If, as a matter of fact, Dr. GRIEVE, who says he has followed the discussions on this subject with close attention, does not understand the elementary difference between that which in England goes by the name of "medical inspection," which aims at isolation and disinfection, and that which constitutes quarantine as understood and practised abroad, it may be that others also do not clearly perceive the distinction. And since at this moment the subject is matter of discussion between the principal Governments of Europe, it may be well to explain that the essential difference lies in the fact that under the English system only those who are found to be actually suffering from the disease to be controlled, or who are so ailing that they are suspected to be so suffering, can be detained; whereas the remainder of the crews and passengers are allowed to travel to their destinations subject to notice of their impending arrival being given to the authorities at those destinations. In short, the healthy are not detained. Under the quarantine system the healthy are detained, as well as the sick and the truly suspect, and the system, as hitherto practised in most parts of Europe and in the Red Sea, has been carried out in such a way as to expose the healthy to a risk of contracting the disease which it is proposed to check far beyond any which they had run before; the consequence being that the detention has to be renewed again and again until a sufficient period has elapsed since the last of the hitherto healthy who will sicken has succumbed to the disease. Dr. GRIEVE claims that quarantine does much the same as our English system because it, too, only aims at "detention and isolation of sick persons, and also, but separately, of suspects." But the quarantine system regards all the healthy on board as suspect, whereas the English system regards all as healthy who are not actually suffering from some definite ailment, and it deals with them as such. We need hardly point out that the difference is a vital one. Again and again we have been told that our fears as to the consequences to the healthy are imaginary. Here in England it is essentially cholera with which we are concerned, and the glorious climate of El Tor in the Red Sea, and the careful arrangements, including the grouping of the healthy into classes so as to avoid risk, are constantly dangled before our eyes as something to be grateful for. We always knew the facts were diametrically opposed to the professions made, but we are glad to have before us at this moment Dr. PAUL KAUFMANN'S "Die Quarantäne Station El Tor,"[1] for in it the tale, which gives the facts up to date, is told by one who cannot be suspected of English bias. We should advise all who wish fully to apprehend the bearings of this question to procure the book and read it; and in the meantime we would only refer to the description given in it of the water-supply, which, after so long a term of years, is available in this noted sanatorium, for a wholesome water-supply will be admitted by all to be a first requisite in the case of a cholera quarantine station. Dr. KAUFMANN, who is gifted with a vein of humour, recalls the fact that near El Tor were the bitter waters of Mara, the taste of which led to the Israelitish murmurings against MOSES; and he then states that if the Israelites had had such stuff offered them as obtains at the El Tor sanatorium they would not have contented themselves with murmurs, but they would certainly have stoned their leader.

But, as we said at first, we have no wish to dispute Dr. GRIEVE'S contention in so far as Guiana is concerned, for he frankly admits that what he claims for that colony would not be properly applicable to England or to any European country; and we are at one with him that, theoretically at least, quarantine can control and restrain infection. He desires to deal by quarantine with most infectious diseases, and he explains that the colony consists of a population scattered over a wilderness, without any sanitary supervision, and where vaccination is all but unknown. Should infectious disease be landed under such circumstances, the first intimation of it that would be received would be "a widespread outbreak of disease which it would be a hopeless task to check." In a country where there is no profession even of a sanitary administration, and where the well-known prophylactic against small-pox is not and never has been practised, we can understand the attitude adopted, and we have no desire to cavil at it. The address was mainly interesting to us in so far as it bore upon the European attitude towards quarantine in its relation to cholera.

FOR many years a mysterious disease has affected cattle in that part of the American Continent which borders on the Mexican Gulf and is known in the United States as the splenic, Texas, or Spanish fever. It has been observed wherever and whenever bovines from the States on that Gulf have been driven northwards, and more particularly during the summer months, and is looked upon with the greatest apprehension by cattle breeders. In 1868, for

[1] Berlin, 1892. Verlag von August Hirschwald, 68, Unter den Linden.

Digitized by Google

instance, the destruction it wrought among the northern herds with which the travelling Texan droves came in contact, directly or indirectly, and the obscurity that prevailed with regard to the nature of the disease, caused a serious panic, and nearly led to the total suppression of the traffic in cattle between the Gulf States (which are almost entirely cattle-rearing countries) and the Northern States. At that time Professor GAMGEE was in America, and the United States Government availed itself of his services in making an investigation of the malady. The report of the Commission was published in 1871, and did not throw much light either on the nature of this Texas fever, as it is now generally designated, or its etiology; indeed the latter remained in as great obscurity as ever. The tendency was to regard it as a kind of anthrax or splenic fever, due to the animals becoming affected by something in the soil or water; "their systems became charged with poisonous principles that accumulated in the bodies of acclimatised animals, which enjoyed immunity from the disorder." It was ascertained that these southern cattle might be taken great distances, and improve in condition while doing so, and yet for some weeks, and probably for as long as three months, they would "continue to excrete the deleterious principles which poison the cattle of the States through which the herds are driven on their way north or west." The report also stated that all breeds of cattle in States north of those of the Gulf coast, without regard to age or sex, if they fed on grass contaminated by southern droves, were attacked by the fever; that it occurred chiefly during the hot months of summer and autumn; and that infected pastures were rendered free from danger by frosts, and remained so until fresh droves of Texan or Florida cattle were again driven over them.

This apparent freedom of the exotic southern cattle from disease, and their capability, notwithstanding, of disseminating such a fatal infection among native bovines, was an altogether unusual feature in epizoötology, and could not be accounted for. It is true that the redoubtable cattle plague, or rinderpest, does not so severely affect the cattle of southern Russia as it does those in western countries; yet it kills a good percentage of them, and greatly impairs the condition of those which do not succumb. But here were animals in evidently excellent health carrying destruction everywhere they went.

The principal symptoms in those infected are a somewhat rapid rise of temperature from 101° or 102° to 106° and 107°, at which it remains from four to fifteen days in fatal cases; this condition is soon accompanied by intense debility, that persists until death takes place. A few days before the fatal termination the urine becomes more or less deeply tinged with hæmoglobin, and the destruction of red blood-corpuscles causing this altered tint of the urine can be demonstrated by examining the blood obtained from an incision in the skin. In acute cases, a day previous to death the number of these corpuscles has been found reduced to about one million in a cubic centimetre of blood, the normal number being something like five millions and a half. In one case, which recovered, the corpuscles fell to nearly one-half their ordinary number, and a week later they had not increased to three millions. This enormous decrease in the red corpuscles gives the blood an exceedingly thin and watery appearance; after death it coagulates rapidly, and forms clots of unusual firmness.

The lesions noted in making a necropsy are chiefly the following: The spleen is very much enlarged, and when incised the tense capsule retracts, and exposes a dark-red and more or less disorganised pulp that sometimes pours out as a semi-fluid mass; this engorgement is due chiefly to the presence of an immense number of red corpuscles. The liver is much affected; it is yellowish-brown in colour, the tissue is deeply bile-stained, and the smallest canaliculi are often plugged with inspissated bile, that fluid in the gall-bladder being also so thick that it scarcely flows, owing to the presence of solids in the form of minute yellow flakes. The kidneys are tinged with hæmoglobin, the connective tissue around them being distended with reddish serum. The other organs are often more or less stained in the same manner, but seldom exhibit any other character.

The heavy losses caused every year by this peculiar fever have compelled the United States Government to take special notice of it, and with the view of thoroughly investigating its pathology, experimental stations have been established at points where it could be best observed. The result of this measure has been very satisfactory. These investigations began in 1889, and attention was more especially directed to the blood. No bacteria were discovered, but there were found, instead, peculiar bodies lodged in the red corpuscles. In the fresh splenic pulp these appeared as round or oval, almost colourless spots, from one-half to nearly two micro-millimetres—from $\frac{1}{3000}$ to $\frac{1}{1200}$ inch—in diameter on the disc of the red corpuscles, and always somewhat excentrically placed. Sometimes there was only one but quite commonly there were two, and very rarely three or four, in the same corpuscle. In organs kept in the cold for nearly two weeks these bodies were still visible, though faintly so, owing to the diffusion of the hæmoglobin around, and perhaps into them. They stained with aniline dyes as readily as nuclei and bacteria, and retained the stain as tenaciously; they then appeared like deeply stained cocci, about one-half to one micromillimetre in diameter, situated within the unstained circle of the corpuscle. Besides the spherical forms, ovoid bodies are not uncommon, and these usually occur in pairs within the red corpuscle; while a still rarer pear-shaped form is met with in stained preparations of the blood, this being rounded at one pole and constricted or filamentous at the other. These almost invariably occurred in pairs, which occupied one corpuscle, and were considered as the result of division of the single body. Another abnormal form was found in the blood. When dried cover-glass preparations were stained with LÖFFLER'S alkaline methylene blue, a few corpuscles appeared as if their surface had been dusted over with minute specks of colouring matter; but whether these were due to the anæmia, or whether they belonged to the cycle of the micro-organism, could not be determined. Very few of these bodies were found in the circulating blood, though in one instance a number were detected in that fluid the day before death. Blood from the right ventricle of the heart contained them in enormous numbers in pairs within the red corpuscles. They seemed to be filtered out by the spleen and liver, for they might be numerous in one or both of these organs, and rare in blood from the

Digitized by Google

right heart. They appeared to be more abundant in the spleen than in the liver. In perhaps half the number of cases examined, they were so few in the spleen that they easily escaped the attention of an observer searching for bacteria. In one instance they were so scarce that a number of fields had to be scanned before any were detected, and here the spleen was completely disintegrated; while the urine, which contained much hæmoglobin several days before death, was almost normal in colour at the necropsy, as if the animal had overcome the parasites, but perished from the havoc caused by them.

It had *long* been suspected by cattle owners that the appearance of this fever in northern cattle was in some way connected with the ticks (*Ixodes Americanus*, Lat.; *I. bovis*, Riley) distributed by southern cattle, though this notion was generally scouted by scientific men. However, as every other possible cause of the scourge had evaded detection, it seemed worthy of investigation, and the result now is that indisputable evidence has been obtained that the fever is produced by these ectozoa. Ticks taken from the bodies of southern cattle, and placed upon pastures which could have been contaminated in no other way, so infected these grounds that susceptible bovines placed upon them contracted the malady in the same period of time, and were as seriously affected, as were other susceptible cattle allowed to consort with those from Texas. Again, young ticks that were hatched from the eggs of adult ticks picked from southern cattle were placed on the skins of northern animals, and induced the disease.

There are, consequently, two factors in the production of Texas fever—ixodes, and the protozoal micro-organism which is located in, and destroys the red corpuscles of, the blood in the affected animal. Whence the insect obtains the protozoon is not yet known, but that the latter can be transmitted from one generation of ticks to another, through the ova, has been demonstrated. It is important to know how many generations of ticks these germs can be communicated to without losing their virulence, and whether there is any other means by which they gain access to the blood of cattle than by the punctures made by these vermin. There are evidently ticks which do not bear the micro-organisms, as cattle which are susceptible to Texas fever are often badly infested with them without showing any marked signs of bad health. On the other hand, there may be means by which the protozoon gains access to the blood of cattle independently of the agency of ticks; but it appears from the investigations just reported, that in the great majority of cases cattle are infected by means of the skin parasites. The adult ticks drop from the southern cattle, and deposit their ova upon the pastures; these ova are hatched, and the young ticks get on susceptible beasts and engender the disease in them. The young ticks are hatched within from fifteen to thirty days after the eggs are laid, and at once get on the cattle, where they become mature within from twenty to thirty days; they then fall off lay their eggs, and die. This process goes on continuously until the cold weather sets in.

The experiments by which these interesting and important results were arrived at, were numerous and conclusive as to the part the ectozoa play in the production of the malady, so that it might be said, No ticks, no Texas fever. Is it not possible that the Tse-tse fly of Central and South Africa causes the death of certain mammalia by acting as the intermediate bearer of a noxious micro-organism, as the mosquito does with regard to the filaria sanguinis hominis? In no other way, it would seem, can its deadly action be accounted for.

DOES the tendency, increasing, we are told, in continental schools, to minimise the study of pharmacy in medical qualification receive any warrant from the best periods of medical practice? We think not; and Dr. BERENDES, in his recent "History of Pharmacy," gives exhaustive grounds for an answer in the negative. CELSUS, in a memorable passage of the introduction to his "De Medicina," says of the Alexandrian school that it had split up the healing art into three branches—the dietetic, the pharmaceutical, and the surgical. From his statement historians have concluded that this tripartite division of medicine involved a complete separation of each section from the other; that the practitioner who relied on dietetics had nothing to do with drugs; that his contemporary who based his practice on drugs ignored diet; and that, while neither paid any heed to surgery, the surgeon held both of them at arm's length. HALLER is one of the upholders of this view. "About the time of HEROPHILUS and ERASISTRATUS," he says, "surgery and pharmacy broke away from dietetics. This was a gain to botany, for the pharmaceutist threw himself with undivided energy into the study of plants; but, on the other hand, medicine proper was the loser, as the leading consultants neglected the vegetable kingdom, and administered remedial agents sold by quacks." SPRENGEL, another learned historian of the healing art, expresses himself in almost the same terms. Medicine, he says, as CELSUS assures us, was so modified by the Alexandrian school that its practitioners separated themselves completely from surgery on the one hand, and from the knowledge and preparation of drugs on the other. While the learned *dilettanti* of the profession were too proud or too lazy to meddle with arts which in their eyes were beneath their dignity, the old "rhizotomy" (medical botany) revived, and, in conjunction with pharmacy, was worked up into a *métier* by individuals. These interpretations, as Dr. BERENDES has shown, are, both of them, unwarranted. CELSUS, when he speaks of combating disease by pharmaceutical means, is not thinking of the knowledge and preparation of drugs. He is simply opposing to that school of practitioners who had chiefly faith in diet that other school who relied most on active remedial agents. This is clearly his purpose, as may further be proved from the preface to the fifth book of the "De Medicina." Diet and drugs, he says—indeed, all parts of the healing art,—are so closely interdependent that neither can be separated from the other. GALEN, about 130 years later, is of precisely the same opinion. "Pharmacy," he maintains, "heals, with medicaments only, internal and external lesions." That it had an independent existence, in the modern sense of the term, or, as SPRENGEL would have it, as a mere auxiliary of the physician, is, as Dr. BERENDES justly remarks, a totally false assumption. SPRENGEL'S further contention that it took the place of an effete "rhizotomy" is equally un-

Digitized by Google

fever. Is it not possible that the Tse-tse fly of Central South Africa causes the death of certain animals by acting as the intermediate bearer of a germ to the organism, as the mosquito does with regard to the sanguinis hominis? In no other way, it would seem, can its deadly action be accounted for.

DOES the tendency, increasing, we are told, in certain schools, to minimise the study of pharmacy in its qualification receive any warrant from the best practice? We think not; and Dr. BERENDES, in his recent "History of Pharmacy," gives exhaustive reasons for an answer in the negative. CELSUS, in a remarkable passage of the introduction to his "De Medicina," tells us that the Alexandrian school that it had split up the healing art into three branches—the dietetic, the pharmaceutical, and the surgical. From his statement historians have concluded that this tripartite division of medicine implied a complete separation of each section from the other; that the practitioner who relied on dietetics had nothing to do with drugs; that his contemporary who based his cure on drugs ignored diet; and that, while neither paid any attention to surgery, the surgeon held both of them at arm's length. HALLER is one of the upholders of this view. "Since the time of HEROPHILUS and ERASISTRATUS," he says, "surgery and pharmacy broke away from dietetics. This was due to botany, for the pharmaceutist threw himself with divided energy into the study of plants; but, on the other hand, medicine proper was the loser, as the physicians sultants neglected the vegetable kingdom, and almost remedial agents sold by quacks." SPRENGEL, another historian of the healing art, expresses himself in the same terms. Medicine, he says, as CELSUS says was so modified by the Alexandrian school that the titioners separated themselves completely from on the one hand, and from the knowledge paration of drugs on the other. While the *dilettanti* of the profession were too proud to meddle with arts which in their eyes were lowering dignity, the old "rhizotomy" (medical botany) and, in conjunction with pharmacy, was worked by *metier* by individuals. These interpretations BERENDES has shown, are, both of them, ceutical means, is not thinking of the knowledge paration of drugs. He is simply opposing of practitioners who had chiefly faith in diet school who relied most on active remedial agents. clearly his purpose, as may further be proved face to the fifth book of the "De Medicina," drugs, he says—indeed, all parts of the healing so closely interdependent that neither can be separated the other. GALEN, about 130 years later, is of same opinion. "Pharmacy," he maintains, medicaments only, internal and external had an independent existence, in the modern term, or, as SPRENGEL would have it, as a mere

---

tenable. Rhizotomy was still in great vogue immediately before and long after the rise of the Alexandrian school. Indeed, GALEN, even in his time, repeatedly praises the rhizotomist ANTONIUS for his knowledge of healing plants; and makes mention of another of the fraternity, PHARNAKES by name, as having taught him a wonderful remedy in hepatic diseases. The preparation of medicines was, as GALEN expressly lays down, "a privilege of the physician," to be exercised only with the best materials that could be procured. PLINY the Elder, a century and more before GALEN, even goes so far as to specify the best quality of stone which the physician should employ for his mortar. HALLER'S attempt to show that the Alexandrine practitioners who combated disease with drugs were in the narrow sense "pharmacopolæ" rests on a passage of PLINY which has really no bearing on the question. PLINY is denouncing the indolence of Roman consultants who, having neglected to qualify themselves for the composition of the drugs they prescribe, rely on the quack vendors of these, who hawk them ready made. Then, as in much later times, there were perfunctory practitioners who liked to have everything done for them, and who, as PLINY says of the stipendiaries of the Alexandrian University, found it far more to their taste to sit on benches and philosophise than acquaint themselves with the remedial virtues of the vegetable kingdom. Dr. BERENDES points out that in modern schools there is a tendency not dissimilar to that in the Egyptian *alma mater*, and that a neglect of pharmacy on its practical side would fain justify itself by an appeal to historical precedent. No such precedent, at least in the sounder phases of the healing art, can be adduced—certainly not from the precept or practice of the "fathers of medicine." There is no "royal road" for the physician any more than for the geometer; and specialism could assume no more objectionable form than the disparagement in medical qualification of that practical familiarity with drugs, their composition and their preparation, which has hitherto been insisted on as an integral and not the least important part of the practitioner's training.

THE pathology of pneumonia is one of the *quæstiones vexatæ* of medicine. The disease has so many points of resemblance, on the one hand, to the specific fevers, and, on the other, to acute pulmonary affections, that the determination of its true pathological relations is a most difficult and complex problem. The question at issue becomes still more interesting when we remember that, not only has pneumonia been a puzzle to the pathologist, but its treatment has been one of the great controversies of therapeutics. We naturally turn for light on these subjects to such a work as the exhaustive "Treatise on Diseases of the Lungs and Pleura," by the late Dr. WILSON FOX. "Two opposite theories," the author informs us, "have been advanced regarding the origin of pneumonia, both of which are supported by certain facts and opposed by others—(1) That pneumonia is a 'specific' fever, of which the disease in the lungs is only a local effect; and (2) that it is a purely local disease, of which the pyrexial and other phenomena observed are only the immediate consequences." In favour of the first view are the following facts—(*a*) negatively, the absence in a large proportion of cases of any discoverable cause likely to excite inflammation of the lungs, and (*b*) positively, the suddenness of the onset of the disease, its well-defined course, its occasional epidemic and contagious character, the presence of bacteria in the blood, and the frequent appearance of a cutaneous affection (herpes), possibly analogous to the rash of the exanthemata. A point corroborative of the above is the well-known want of synchronism between the clinical progress of the case and the pulmonary condition. Thus, it is very common for the temperature to fall to normal and all the symptoms to abate, while the physical signs of pulmonary consolidation remain practically unchanged. Less frequently, but still not very rarely, the consolidation may show signs of resolution before there has been any abatement of the clinical symptoms.

The above evidence seems strong, and if we confined our attention to it we might conclude with some confidence that pneumonia must take its place among the "specific" diseases. But, unfortunately, there are some points of great weight that tell against this view. Thus pneumonia is only very exceptionally epidemic, and its contagiousness, although held by some good observers, is still doubtful. Again, the influence of season is very apparent. The preponderance of pneumonia falling in the months from January to May. It might be urged, in reply to this, that just as pneumonia shows a preference for the late winter and early spring, so typhoid fever inclines to occur as an autumnal disease. But it seems impossible to resist the evidence that the frequency of pneumonia is much influenced not only by season, but by weather, cold winds, and sudden changes of temperature predisposing to it. In this regard, pneumonia shows an affinity with pulmonary disease and other affections that are admittedly due to "chill." Then, again, while there is often a want of synchronism between the physical signs and the symptoms of pneumonia, we have to recognise, on the other hand, such a fact as the greatly increased mortality which attends bilateral, as opposed to unilateral, pneumonia.

In so far as treatment throws any light on this subject there are facts on both sides. The general stimulant treatment of pneumonia, now almost universally adopted, hardly differs essentially from the treatment of the continued fevers, and is obviously adapted rather to the theory that pneumonia is a "specific" disease than to the belief that it is a local inflammation. On the other hand, local applications to the chest in the form of poultices, icebags, &c., have enjoyed much favour, and have been believed by some authorities to influence the progress of the disease. Stimulating expectorants, again, generally play a considerable part in the therapeutics of pneumonia. Summing up the subject, WILSON FOX wrote: "The theory of a 'specific' cause can scarcely be maintained for pneumonia in the same sense as that in which the term is employed for the contagious pyrexial diseases. The causes of pneumonia are manifold, and the disease may originate under such diverse conditions that it seems impossible to attribute it to any single blood poison. On the other hand, the most probable hypothesis to explain its origin is that of an altered composition of, or the existence of some morbid material in, the blood, which, from its special qualities, may affect a particular organ, or, as is more probable, may,

under local predisposing causes, excite inflammation in that part of the system which in any given individual is the most liable to suffer, as a *locus minoris resistentiæ*." We have no knowledge of the nature of the changes in the blood that predispose to pneumonia. The excess of fibrine that has been described has been shown by VIRCHOW to be the consequence, rather than the cause, of the pulmonary inflammation. In some cases, no doubt, pneumonia is due to septicæmia, but this is not at all probable of the typical acute disease.

It is rather a curious circumstance that while theoretical considerations and clinical evidence seem at present inadequate to fix definitely the pathological relations of pneumonia, the response of pathology and bacteriology is also somewhat equivocal. It is true that the researches of the bacteriologist of late years have considerably advanced our knowledge of this part of the subject. From them we learn that the microbe most constantly present in pneumonic exudation, and in that of the inflammatory affections with which pneumonia is often complicated, is the diplococcus discovered by FRAENKEL and WEICHSELBAUM; whereas FRIEDLÄNDER'S bacillus, like some other microbes occasionally found in pneumonia, is of exceptional occurrence. Nor must the remarkable investigation of the two KLEMPERERS upon the toxines of the first-named organism be lost sight of, as affording additional proof of the specificity of the disease. Nevertheless, when all these contributions to knowledge are collated, it would still seem that much remains to be done before we are in a position to conclude that bacteriology has said its last word regarding pneumonia.

According to WILSON FOX, "the disorder which, on a lesser scale, presents the greatest analogy with acute pneumonia is perhaps acute tonsillitis, where we have the same short initial stage, a similar intensity of rigor and prostration, a similar sudden invasion of pyrexia, and a similar rapid decline of this before the local inflammation has shown any signs of abatement. In tonsillitis, also, we have frequently an equal difficulty with pneumonia in verifying a distinct cause, and a certain amount of evidence at least exists in the case of the so-called 'hospital sore-throat,' that it may also be produced by other poisons than those originating within the system from the impeded exercise of the function of the skin." It will thus be seen that the pathology of pneumonia remains a question *sub judice*, but that the best authorities incline more and more to the specific theory of its origin.

THE statement which has recently been presented to the Scottish Universities Commissioners by the Edinburgh Association for the Promotion of Reform in Medical Education in the University of Edinburgh must necessarily lead to great changes in the methods of medical education in that University. The number of medical students in 1889–90 was 2003; the number of professors in the medical faculty is twelve. Evidently in order to keep pace with modern requirements in the teaching of medicine, the number of lecturers, assistants, and demonstrators has been greatly increased, and to these gentlemen the arrangement and control of the practical classes, which demand the utmost attention and the greatest amount of work, have been virtually assigned. It is stated that at the present time even these are insufficient in number to attend to the wants of the students. Instead of meeting the necessary differentiation in teaching involved in the increased range of medical study, it is urged that at Edinburgh practical and tutorial classes are arranged under professors who may have no knowledge of these new departures, and yet exercise full control over the assistants and demonstrators by whom the teaching is conducted, and that in many cases the majority of students are not properly instructed in the more modern methods of investigation and research. To such a pitch of conservatism has the education of medical students reached that we are told in a memorandum that this differentiation "is largely unprovided for, and certainly so to an extent greater than is the case in many small English schools, in the unendowed extra-mural school of Edinburgh, and even in the smaller foreign universities." The great burden of complaint is, in the first place, that the teaching is insufficient and its rewards are in too few hands. As we have said, the University works its medical school of 2033 students by means of twelve professors (seven of whom are also engaged in private practice), five lecturers (of whom four are also in private practice), and about thirty assistants, who do the main part of the practical work. It is obvious that the growing demands in medical teaching during the past twenty years should have been met by a proper increase in the professoriate, and not by handing over such duties to a junior, and an insufficiently remunerated, staff controlled by the respective professors. The class fees paid to the professors in 1889–90 amounted to £23,000, and in 1886–87 the average net income of each was £1620. We know that in many instances it has exceeded this amount, and in addition to the net income the Scotch professor is assured of a handsome retiring allowance. Under these circumstances it is clear that unless the prestige of Scotch University education in Edinburgh, so far as medicine especially is concerned, is to be allowed seriously to deteriorate, a few important reforms are urgent. These are: that the whole teaching staff should be paid directly by the University Court; that all teaching appliances and collections in the museum and laboratories should be the property of the University, and be maintained at its expense; that extra professorships should be established in many subjects; and that a revision and readjustment of the fees should be made, so as to secure a fair remuneration, with a due proportion of the class fees—not determined by the professor, but by the University Court—for the junior workers, viz., the assistants and demonstrators, on whom is really placed the practical work of the University. The system of lecturing to huge classes is in these days really an anomaly; personal supervision of the practical and clinical work of each medical student has now to a great extent superseded the ancient plan, and will still further replace it in the future. A reform in the incidence of the fees must follow this change in medical education, however distasteful this may be to the Scotch professoriate.

"Ne quid nimis."

THE ASSOCIATION OF FELLOWS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE recent action of the Council of the Royal College of Surgeons in appointing a committee to consider what further advantages should be extended to the Fellows of the College has had its natural effect in stimulating the zeal of the committee of the Association of Fellows. The announcement was considered by the officials of the latter body of so much importance that a meeting of the committee was summoned about ten days ago to take the subject into consideration and to determine the future action of the Association. As a result of this summons the members of the committee mustered in strong force on Wednesday last, the 30th ult., at 5 P.M., at the residence of the President, Mr. Pollock. After the minutes of the last meeting had been read and confirmed, the discussion was formally opened by Mr. Holmes, Vice-President of the Association, who had drawn up a digest of the points which the Association has from time to time urged at general meetings of the College. This digest was put into the form of a resolution, proposed by Mr. Holmes and seconded by Mr. Lawson Tait, and was carried by acclamation. It was to the following effect:—"The following points are those which the Association of Fellows regards as essential to the well-being of the College in its relation with its Fellows. We arrange them in the order of their importance, in our opinion: 1. No organic changes in the constitution or relations of the College ought to be decided on without having first been approved by the Fellows of the College. 2. At the annual meeting of the Fellows the President ought to be elected by the votes of the Fellows present. 3. The Fellows ought to have the right to meet at the College separately from the Members. 4. A separate room in the College ought to be set apart for the use of the Fellows. In urging these points we express no opinion on the rights of the Members in any of these respects, seeing that our Association is formed solely for the purpose of advocating the claims of the Fellows." It was further considered desirable that the honorary secretary of the Association should communicate with the President of the College, and state that the committee of the Association would be glad to be allowed to send a deputation to the Council. The discussion of the foregoing subjects occupied the committee for a considerable time, and some other important business, including the consideration of a draft account of the proceedings of the Association of Fellows, which has been drawn up by a subcommittee specially appointed for the purpose, had to be postponed to a subsequent meeting. One other resolution, however, which we have sincere pleasure in recording was unanimously adopted—viz., "That this committee invites Mr. John Tweedy to allow himself to be put in nomination for the Council at the next election." We shall recur to this matter at an early date.

THE RETIREMENT OF DR. HAYCRAFT FROM EDINBURGH UNIVERSITY.

IT is naturally with some reluctance, but not without hope that good may come of it, that we call attention to the unhappy state of affairs at present and lately existing in the University of Edinburgh in connexion with the relations between the holder of one of the most important professorships in the medical faculty and the gentlemen who have lately been assisting him in his work. We will not recal the extremely unpleasant circumstances under which a few years ago the professor parted with his then assistant. Acting on the advice of his friends, the professor took a prolonged rest, and it was earnestly hoped that in the future there might be no recurrences of similar differences. Unfortunately such has not been the case. In the *Scotsman* of March 18th Dr. Berry Haycraft gives a narrative of his relations with Professor Rutherford and the causes of his dismissal. The facts as set forth by Dr. Haycraft are briefly these: In March, 1887, Professor Rutherford wrote to Dr. Haycraft, then occupying a chair in the Mason Science College and the Queen's College Medical School, Birmingham, asking him to be his substitute at Edinburgh during the prolonged absence which his state of health required. Dr. Haycraft was unable to consent, as it would take him away from his office for so long a period; but subsequent correspondence and interviews took place, in the course of which Professor Rutherford appears to have offered him a permanent post as his colleague, and it was understood that he would apply for Dr. Haycraft's appointment as assistant professor when he (Professor Rutherford) returned to Edinburgh. At Professor Rutherford's instance, and with no misgivings, considering their mutual relations, Dr. Haycraft signed an agreement which contained a clause binding the parties mutually for three years, and requiring at least a year's notice if either wished to retire from it. Dr. Haycraft accordingly resigned his Birmingham chair, and took up what he thought to be a permanent office in Edinburgh. About the time of expiry of the three years' agreement, and shortly after Professor Rutherford had assured his colleague of his continued confidence in him and need of his help, a serious change is alleged to have occurred in the attitude of the senior towards the junior professor. Apparently this was excited by the fact that Dr. Haycraft had communicated a paper to the International Congress at Berlin, upon a subject in which Professor Rutherford was also much interested—viz., the structure of striped muscle. The latter gentleman, moreover, is stated to have attempted to sever his connexion with Dr. Haycraft in the middle of the session by reference to the above-mentioned clause in the agreement, but omitting the one year's notice. Dr. Haycraft seems besides to have good reason to complain that owing to various circumstances no steps were taken by Professor Rutherford to obtain for him the status of assistant professor until after the Berlin incident. Pending the action of the Universities' Commission, the Senate declined to make the appointment, and now Dr. Haycraft finds himself severed from his *alma mater*, to which he had been invited on the urgent appeal of his former master. In view of all the facts we feel strongly that it is the bounden duty of the University to make full inquiry into the matter. Whichever way the subject is viewed it is impossible to avoid sympathising with Dr. Haycraft, who, by his own action, and in all good faith, has placed himself beyond the power of obtaining legal redress.

MEDICAL PRESCRIPTIONS AND DRUGGISTS.

THIS perennial subject has lately been discussed in letters in the *Pharmaceutical Journal*. The medical writers complain that old prescriptions are redispensed by chemists over and over again, often when the condition and case of the patient make it very unsuitable and even dangerous. The chemists recommend as a remedy for this that the medical practitioner who wishes to cease dispensing should retain a particular chemist, and have an understanding with him not to dispense particular prescriptions more than once and without special authorisation. This is an arrangement that may be worked honourably on both sides. But it is not so satisfactory as one in which the practitioner is independent

Digitized by Google

of all chemists and the patient pays for the prescription. After all, if the patient uses a prescription on another occasion than that on which it was prescribed, he does so at his own risk. But it is undeniable that a prescription given to the patient for a fee is his property, to be used by him at his discretion. To think that Parliament, as is suggested, could be got to pass an Act to stop this practice is to have much more faith in Parliament than seems to be warranted. Speaking candidly, these letters are not very practical. There is one evil which they entirely ignore, and which is of far graver import than those complained of—viz., the assumption of an air of medical knowledge and learning by druggists in cases that would puzzle medical men themselves; and the use to which they put their familiarity with prescriptions—viz., repeating them for others and prescribing them. Some druggists—we should be sorry to think more than a few,—by a system of inquiry learn the general nature of the cases for which prescriptions are written, and then apply them to what they regard as similar cases. If general practitioners and chemists are to come to better relations, there must be a more perfect and delicate understanding on such practices.

THE MEDICAL REGISTERS FOR 1892.

THE Medical, the Dental, and the Medical Students' Registers, printed for the General Medical Council at Her Majesty's Stationery Office, are now ready. The election of direct representatives necessitated the revision of the Register with more than ordinary care. The number of practitioners registered during 1891 has somewhat increased, being 1345, as against 1266 in 1890. Deducting those names which have been removed from the Register owing to death or from other causes, the number of names added to the Register is 392. The total number is 29,555, as against 29,163 in the previous year. Of the new registrations, 683 were effected in England, 502 in Scotland, and 160 in Ireland. The registration of colonial practitioners under Part II. of the Medical Act, 1886, now includes 10 names. The Dentists' Register for 1892 will be found to contain 79 persons more than that for 1891, making a total of 4896, of whom 1179 practitioners, or 24·07 per cent., possess the qualification of Licentiate in Dental Surgery; while 3698, or 75·55 per cent., are registered as "in practice before July 22nd, 1878." This shows a marked diminution continuously going on from the percentage 90·87 of those who were so registered in the year 1879. The number of foreign dentists now registered is 19, or nearly 0·4 per cent. The Medical Students' Register shows that 2405 students registered in 1891. This is the maximum hitherto recorded, being 559 more than in 1890. This may be accounted for, no doubt, by the new regulations with regard to the five years' curriculum that came into operation on January 1st, 1892. Following the practice adopted for many years past, statistics are given showing the respective preliminary examinations that these students passed and the various medical schools or other "places of study" at which they commenced their professional career.

MEDICAL LEGISLATION IN NEW SOUTH WALES.

THE Sydney papers, in leading articles and letters, continue to discuss the Medical Bill and its fitness to secure the chief ends of medical legislation—the clear differentiation of the qualified from the unqualified. The *Sydney Morning Herald* objects that, while special arrangements are made for the registration of persons who have been practising without qualification, men who have passed through a curriculum and who hold qualifications or degrees may be left out or remain unregistered. There is some ground for the first objection. When medical legislation was first introduced it was reasonable to admit to the Register persons actually in practice and without diplomas. But that can hardly be held now, when for many years, in most civilised communities, men have been required to show proof, in the shape of diplomas, of being qualified to practise. At any rate, if there is still to be a clause of grace in favour of men without diplomas, it should provide that they shall be registered under a separate head, not on the score of possessing a diploma, but on giving satisfactory proof of having been for many years in practice. To make clear such a distinction is only fair to men who have taken diplomas at great cost of time and money, and fair also to the public. The *Herald* also objects, apparently, to registered men being disfranchised or taken off the Register on the ground of their diploma being taken away by the body that gave it on the score of mere "misconduct" or a breach of professional etiquette. Our contemporary would surely admit two things. First, that "conduct" is an essential element in the worth, and even the qualification, of a medical man. If a man dissociates himself from the obligations of his profession and its methods, he has no right to complain if his profession disowns him. It is in the public interest that he should be disowned. Medicine is a calling in which public deception and fraud can easily be practised if once the honourable and ethical side of it be disregarded. The second point is that no persons are so fit to judge in such a matter, and so likely to judge mercifully, as those composing the body from which the diploma proceeds. By all means let the Medical Council be required to deal directly with charges of misconduct, and to judge for itself; but in any case the judgment of a man's *alma mater* should count for much, and its disciplinary powers should be upheld. It is true, as our Sydney contemporary points out, that the Universities which should be most exemplary in the use of their disciplinary powers cease to have any after graduation. This is a monstrous state of matters, from which it results that graduates of ancient and honourable Universities occasionally bring their *alma mater* into great discredit with impunity. But that is a reason for giving to all bodies which grant diplomas full disciplinary powers, not for withdrawing them from those which already possess them. It is noticeable, as pointed out by a correspondent in the *Sydney Daily Telegraph*, that the judicial powers of examining bodies are only contemned by those who fear the exercise of them.

THE USE OF COCAINE IN SURGERY.

AT the Islington Medical Society recently Dr. Woodroffe read a paper on the Use of Cocaine in Surgery. He wondered how general practitioners got on formerly without it. He specified the following cases in which he had used it with satisfactory results—nasal polypi, adenoma of the naso-pharynx, excision of the tonsils, cystic growths of the scalp, tarsal cysts, scraping out of tubercular abscesses and sinuses in the neck, small false aneurysm in the palm, villous growth in the female urethra, internal hæmorrhoids, fistula in ano, tenotomy of anterior and posterior tibial muscles, also of the ligamentous sternal insertion of the sterno-mastoid in wryneck, fissure in ano, and abscesses of various kinds. Dr. Woodroffe would never use a general anæsthetic for internal piles save at the direct request of the patient. The expulsive power is saved by cocaine, and is a great advantage to the surgeon. He injects separately into the base of each pile. He has never used more than one grain, generally half that quantity. He had had two cases of poisonous effect, and had come to the conclusion that such a result depends far more on idiosyncrasy than on the quantity of the drug used. In one the quantity injected was half a grain; in the other only a quarter. The first was a woman, the second a girl about fifteen. Such cases have led him to be cautious in

using the drug for women, and especially those of a neurotic type. These symptoms appear immediately after injection. He never injects more than half a grain, and waits two or three minutes before repeating the injection in cases where a large dose is required. In this way he has used two grains without bad symptoms; indeed, he had never seen any symptom supervene which did not show itself on administering the first dose. Of the poisonous symptoms, the most evident were pallor of the face, dilatation of the pupils, sense of impending death, with great restlessness, orthopnœa, very rapid cardiac action; the pulse, however, being less compressible, and the second cardiac sound being more marked than in a syncopal attack. These symptoms were followed by perspirations, and in the case of the girl by rambling, incoherent talk for some hours. The treatment adopted was the inhalation of ether and ammonia, with repeated doses of hot brandy-and-water. Dr. Woodroffe has not found it effective in ear operations or in avulsion of the toe-nail. For the latter he adheres to the use of ether spray. He also praised the use of cocaine (about two grains of the salt in cocoa butter as a flat suppository), coupled with doses of chloral, in the rigid os of primiparæ. It can easily be slipped inside the os and retained there till dissolved.

A HEAVY SENTENCE FOR BABY FARMING.

To whatever cause we may attribute the fact, it is satisfactory to note that, notwithstanding the increased vigilance of the authorities, we have lately heard but little of the evil of baby farming. That it still maintains a surreptitious, though less vigorous, life is unhappily certain, and this, as the report of the following case will show, has lost none of its familiar accompaniments of neglect and cruelty. The later surviving child of two entrusted to the keeping of Alice Hockley, who was recently convicted of manslaughter at Exeter Assizes, was indeed a pitiable wreck when at last released from his sufferings by death. At sixteen months he weighed 11 lb. 2 oz. Both arms and a thigh were broken. His allowance of one pint of milk was shared by four other persons. He had, of course, no medical attendance. Here the responsibility for maltreatment does not appear to have rested on his parent, who allowed four shillings weekly for his maintenance, and who seems to have done what she could for his welfare. In such a case, which is hardly distinguishable from actual murder, the penalty inflicted—twelve years' penal servitude—was well deserved. It should serve to caution any persons who may undertake the care of nurse children that the Act which regulates their conduct will be strictly enforced. It should also remind the agents of local authorities, of the Society for the Prevention of Cruelty to Children, and all others directly interested in the working of the Act, that the wickedness which it combats is by no means extinct, and can only be held in check by their own repressive energy.

TEMPERATURE EXPERIMENTS.

COMING so soon after the honour bestowed on Professor Cannizzaro by the Royal Society, the selection of Professor Mosso of Turin to deliver a lecture before the same learned body has given much gratification to our Italian contemporaries. They note the fact that it is "la prima volta che uno scienziato Italiano viene chiamato a questo onore" (the first time an Italian *savant* has ever been invested with the honour). Having referred to the distinguished audience assembled on the occasion, they summarise Professor Mosso's remarks on the phenomena, psychical as well as physical, associated with the temperature of the brain. In his observations Professor Mosso used exceedingly delicate mercurial thermometers, so that a change of not more than 0·002° C. could be easily measured, and the temperature of the brain was compared with that of the arterial blood, the muscles, the rectum, and the uterus. The subjects of the observations were animals under various narcotics or anæsthetics and also man. He found that, as a rule, the temperature of the brain is lower than that of the rectum, but that intense psychical processes or the action of exciting chemical substances may cause the temperature of the brain to remain 0·2° or 0·3° C. higher than that of the rectum. An ordinary interrupted current causes a rise in the temperature, which is observed earlier in the brain than elsewhere, and in a dog placed under the influence of curare the temperature of the brain remained fairly high while that of the muscles and blood fell. This difference in temperature was always distinct, and Professor Mosso calls attention to the fact which this seems to signify—viz., that muscle is not the only thermogenic tissue of the body. Observations made on an animal when awake seem to show that the development of heat due to cerebral metabolism is considerable, and that the mere maintenance of consciousness belonging to the wakeful state, apart from all intense psychical activity, involves very considerable chemical action and consequent change in temperature. But the variations of temperature as a result of attention, or of pain, or other sensations, are very small; and when an animal is conscious, no change of consciousness, no psychical activity, however brought about experimentally, produces more than a slight effect on the temperature of the brain. Experiments were also made to show the elective action of narcotics on the brain. Thus, if a dog be rendered completely insensible by an anæsthetic, no rise of temperature is obtained upon stimulating the cortex electrically. Again, if an animal be fully under the influence of chloral, and if a muscle be made to contract, the temperature of the muscle rises, but falls rapidly as soon as the stimulation ceases; yet a similar stimulus to a brain under the same conditions will cause a rise in temperature which may continue to increase for several minutes after the cessation of the stimulation. The injection of cocaine also produces a rise in the temperature of the brain without any accompanying change in the muscles, yet when these are rendered inert by curare, the rise in the temperature of the brain after the injection of cocaine is very much greater, as much as 4° C. The observations are, it will be seen, very interesting and suggestive.

DENHOLM v. TAIT.

IN this action Mr. Lawson Tait was the defendant, and the plaintiff was Dr. Denholm of Manchester. As it was not allowed to proceed to the usual termination—a verdict—we need scarcely trouble our readers with the particulars. Speaking very generally, it was a case of myoma in the practice of Dr. Denholm. Dr. Denholm had attended the patient for ten or twelve years, and eleven years ago found her to be suffering from fibroid tumour. This was occasionally inconvenient from its size. Mr. Whitehead and Dr. Lloyd Roberts were both consulted, and the Apostoli treatment by electrolysis was tried, but ineffectually. On one of the occasions on which this treatment was tried an accident occurred which caused a fistula. Finally Mr. Tait was consulted, and recommended an operation, with much promise of success. On Jan. 28th he removed the tumour, which weighed 12 lb. The patient died in forty-four hours. Mr. Tait, in a letter, attributed the untoward result to hæmorrhage, a result of sloughing from the electrical treatment. Dr. Denholm took this letter as a reflection on his treatment, and commenced the action, though clearly he was not responsible for the electrical treatment so much as the consultants who recommended and carried it out. A post-mortem examination was made, to which, unfortunately, Mr. Tait was not invited, as he should have been, and death was shown to have resulted

Digitized by Google

not from hæmorrhage, but from peritonitis. Mr. Tait at the trial still spoke as if he believed that a hæmatocele existed, and might have been found if looked for. After Mr. Tait's evidence lunch time had arrived, and all the parties concerned came to an understanding to withdraw the case, if not the imputations on which the case rested. We cannot say that this course is satisfactory. It leaves questions of great scientific and personal interest unsettled, and must leave on the public mind a painful impression of uncertainty. Such cases must occur, and every practitioner concerned should magnanimously bear his share of the responsibility, knowing that he is doing his best, and giving credit to others for having done the same. Courts of law are rough places for the settlement of such disputes; but, if once appealed to, all the facts should be thrashed out and a verdict taken.

THE MEDICAL OFFICERSHIP OF HEALTH, ISLINGTON.

THE action of the Islington Vestry in suspending its own by-law against appointing actual or recent members to paid offices in favour of Dr. Wynn Westcott has excited general surprise and disapproval. The vacancy was not even advertised. This is a mode of procedure which is altogether out of date. In the House of Commons on Thursday Dr. Farquharson asked the President of the Local Government Board "if he was aware that the Islington Vestry had, contrary to its own by-law, appointed Dr. Wynn Westcott to the office of medical officer of health for Islington, Dr. Westcott having been until March 2nd a member of the Vestry and of the Public Health Committee; whether this appointment was made without previous advertisement, and against the votes of many members of the Board, including the chairman of the Public Health Committee." Mr. Ritchie's reply was in the main affirmative of all the points in the question, but he explained that the appointment was of a temporary nature, and that Dr. Westcott had ceased to be a member of the Vestry and of the Public Health Committee on Feb. 20th. The President gave further particulars with regard to the appointment, but for these we must refer our readers to our Parliamentary report.

METALLIC HYDROSULPHIDES.

QUITE new lines of chemical and physical research are opened in some papers which appear in the February number of the journal of the Chemical Society. The authors, Messrs. S. E. Linder and Harold Picton, of University College, London, who were encouraged and assisted by Professors Ramsay, Carey Foster, and Schäfer, started from an observation in regard to precipitated antimony sulphide. As their papers occupy nearly sixty pages of the journal, it is obviously impossible to present anything but the barest summary. They describe their experiments as still incomplete, but some of the chief conclusions already reached may be stated in a few words. In the first place, it was found that many metallic sulphides, notably those of copper and mercury, were capable of forming hydrosulphides which were soluble, or apparently soluble, in water. In some cases these compounds appear to have definite constitutions with high molecular weights, and we are presented with such curious formulæ as $7CuS,H_2S$; $22CuS,H_2S$; $31HgS,H_2S$; and $62HgS,H_2S$. Such formulæ must evidently be taken as provisional, although there is already fair evidence for some of them. Then followed some very interesting researches on the solutions or pseudo-solutions of these new compounds. In solutions that were apparently clear a beam of light showed the presence of solid particles which settled only with the most extreme slowness. We are reminded here of the experiments made so many years ago by Faraday on the separation of gold from solutions. Although these solutions appeared clear and had a bright-green colour, a cone of light rays showed the presence of suspended solid matter even after years of rest. In some cases these suspended particles were comparatively large, but in others they were so minute as to simulate the phenomena of liquid diffusion. A still more remarkable discovery followed. Using a microscope with an immersion lens capable of magnifying about 1000 diameters, the particles in many cases became visible, and were seen to be in rapid Brownian movement. It is probable that they would have been altogether invisible, but for the short free path produced by their great numbers. In other preparations the particles were far more minute, and it appears that no line of transition can be drawn between a liquid with actively moving solid particles and a true solution. The light which such researches are likely to throw on the complex problem of solution is evident, and scientific men will look forward with great interest to further discoveries.

DEATH OF DR. TOMKINS OF LEICESTER.

WE regret to announce the death on Sunday last of Dr. Henry Tomkins, who for many years held the post of medical officer of health for the town of Leicester. He was educated at Owens College, Manchester, and at Queen's College, Belfast, and afterwards studied at the hospitals of Dublin and Paris. He graduated as M.D. of the Royal University of Ireland in 1877, and in the same year he became a Member of the Royal College of Surgeons of England. Besides his appointment as officer of health he held the position of superintendent of the Fever Hospital, and was also the borough analyst. His yearly reports on the health of Leicester from 1885 were considered models of their kind. THE LANCET was indebted to his pen for several valuable contributions.

EFFECTS OF CRUSHING THE PELVIS TRANSVERSELY.

A SPANISH surgeon, Dr. Arcilza, has made a study of the effects of violent pressure excited in a transverse direction on the pelvis, such as occurs occasionally when a man is caught between the buffers of railway carriages. For the experimental part of his investigations he had constructed a screw-press suited to the shape of the pelvis and fitted with a dynamometer. In this a pelvis with or without the soft parts could be subjected to any required degree of pressure. It was found that the common form of straightening was produced by a pressure varying from 100 to 300 kilogrammes. With less than this the two pubes were pushed forward in a symmetrical manner, but after more than 100 kilogrammes of pressure one of these remained in its position, the increasing deformity being entirely due to the other. At first the bones began to part at the symphysis, and then there came a fracture at the junction of the pubes with the ischium, with complete separation at the symphysis; lastly, the sacro-iliac synchondrosis gave way. Another, though less common, type of injury was fracture of the ileo-pubic and ischio-pubic junctions. A third type consisted of an ischio-pubic fracture with internal displacement of the fractured ends. The most important of the lesions produced in the soft parts were those occurring in the urethra, which is always affected in its membranous portion. Very severe wounds of this were sometimes caused by fragments or splinters of bone. The most usual injury, however, was due to the stretching of the triangular ligament, and consisted of ecchymosis and minute lacerations of some of the coats, but very rarely amounted to complete perforation. This lesion can be recognised by hæmorrhage from the meatus and by the subsequent occurrence of a stricture at the site of the

Digitized by Google

injury. The gravity of urethral ruptures caused by pelvic pressure is due to their producing intra-pelvic extravasation of urine, the only proper treatment for which is hypogastric section. Dr. Areilza details several cases which he has had the opportunity of observing clinically or post mortem, and which correspond with the results arrived at by experiments on the dead subject. In order to understand the mechanism of urethral lesions a special experiment was made on a pelvis from which some of the soft parts had been removed, the perineum, the external genitals, the urethra, the bladder, and the anal extremity of the rectum remaining. The bladder was injected with about eight ounces of water, and the penis tied to prevent its escape. A crushing force was then applied at the level of the acetabula. At 150 kilogrammes the symphysis began to part, and on one side there was lengthening to the extent of 1·5 centimetre. A sound was with difficulty passed into the bladder. At 250 kilogrammes there was overriding of the pubic bones, the lengthening amounting to 3 centimetres, the introduction of an instrument was impossible, though the urethra was sufficiently permeable to allow the water to run out when the bladder was compressed. With a force of 300 kilogrammes there was complete obstruction. The pelvis was now on the point of expressing the bladder from its cavity, and the tissues near the symphysis were infiltrated with venous blood. After the crushing force was removed it was possible, with difficulty, to get an instrument into the bladder, and the fluid could be expressed from it. Experiments were then made with the broken pelvis. These showed that when the displacement was great and the overriding complete the triangular ligament was torn; but the urethra, which is much more elastic, was not ruptured, unless the displacement of the bones was very great. A chromo-lithograph of the urethra is given showing the effect produced by a force of 300 kilogrammes. There was no rupture, though the peri-urethral tissues were lacerated. Several small hæmorrhagic foci appeared in the mucous membrane of the membranous portion and about the veru montanum; hæmorrhagic spots were also found on the bulb.

DR. YARROW AND THE HOLBORN GUARDIANS.

WE remarked some weeks ago on what seemed to us very uncalled-for reflections by certain members of the Holborn Guardians on Dr. Yarrow, who for twenty years has filled the office of medical officer of the City-road Workhouse with much credit and without complaint. Happily these reflections were referred to the Local Government Board. The Board has intimated to the guardians that, after carefully considering all the facts, it has come to the conclusion that Dr. Yarrow is not deserving of blame for his proceedings in the case in question. It is painful to see a public body make such mistakes in the treatment of a respected officer.

COAL-DUST EXPLOSIONS.

THE experiment shown very successfully before the Fellows of the Chemical Society, at the meeting on the 17th ult., by Professor Thorpe, although intended merely as a lecture experiment to illustrate the phenomena of coal-dust explosions, was highly instructive and, in view of the recent colliery disasters, singularly opportune. According to this experiment, coal dust *per se* must be considered beyond question to give rise to explosions of no mean intensity in coal mines. The disastrous effects produced by the enormous force of the impact travelling along all the ramifications of a mine are probably the result of explosions of this class; and the fact that explosions of this character are of rare occurrence in damp mines would seem to bear out this conclusion. Once ignited, the coal dust explodes with great violence, and this violence gathers in intensity as it proceeds. The explosion of coal dust may arise from some local ignition of fire-damp, or from the explosion of a faulty blasting cartridge, especially if the charge is gunpowder. In a box 12 ft. by 6 ft., constructed of oak, and cruciform in shape, an explosion of coal dust was shown, and also one of lycopodium powder; and the path of the explosion, it was pointed out, could be traced by placing pegs on the floor of the chamber, where the quantity of dust gathered on the faces of these pegs could be observed. The farther the pegs are from the initial point of explosion the more dust is observed on them, showing the increased intensity of the explosion as it proceeds. An ingenious apparatus, devised by Mr. Living, a late pupil of the Royal College of Science, for determining the amount of fire-damp in the air of coal mines, was also exhibited to the Fellows. It consists of a small magneto-electric machine, containing two very thin pieces of platinum wire, through which the current is made to pass. One of the wires is fixed in a glass tube containing simply pure air, and the other in a tube through which the air of the mine is drawn. The fire-damp causes the platinum wire to glow more brightly in the latter than in the former. The light is thrown on a paper screen, and by means of a simple device the difference in intensity may be measured and the actual amount of fire-damp deduced. In the interesting discussion that followed Mr. David Howard referred to two cases of "dust" explosions which came within his experience; one had occurred in a mill in which cinchona bark—a by no means inflammable substance—was ground, and in the other case soot produced by the burning of camphor had exploded after the fire had been put out.

ATAXIC PARAMYOTONE.

IN the February number of the *Centralblatt für Nervenheilkunde und Psychiatrie* Dr. Gowers has recorded a curious case under the above title. The patient was a man of forty-one, who had enjoyed good health until a year and a half before he was seen. He had suffered from syphilis eleven years previously—a fact which is probably of some significance. His symptoms first manifested themselves in his legs and later in his arms. When first seen he looked healthy and well nourished, his limbs were large, and his muscles well developed. They showed a peculiar hardness, however, the result of a true tonic spasm, which restricted voluntary movements and rendered them slow and difficult. Both flexors and extensors in arms and legs were affected. The patient would rise slowly and with difficulty from a chair, and would move about with a peculiarly stiff and deliberate gait. He easily fell if he met with any obstacle, and a slight push was sufficient to remove him from the erect position. There was also muscular weakness. But in addition to these symptoms there was also a considerable degree of incoördination of the hands, which made it difficult for him to button his coat and to carry out similar actions. Neither could he tell the position of his limbs, and he could not distinguish different weights. The knee-jerk, and other so-called tendon reflexes, could not be elicited, but this may have been due to the considerable rigidity which was present. There was blunting of sensibility on the palm, as high as the wrist, and slight delay in the conduction of painful impressions, but no disturbance of the temperature sense. The action of the sphincters was not disturbed, and there were no symptoms of psychical derangement. The case, it will be seen, offers some resemblance to one of Thomsen's disease, but differs in that the spasm in the case under notice was persistent, while in Thomsen's disease it is characteristically transitory; but, as Dr. Gowers points out, its importance lies chiefly in the fact that the character of

Digitized by Google

the symptoms makes it certain that the spinal cord is diseased, although, of course, such a view does not exclude a concomitant morbid condition of the peripheral nerves and of the muscles. The existence of a lasting alteration in the function of muscle, depending ultimately on some nutritional derangement, is shown by a change in the electrical and mechanical irritability, as well as by the experimental facts adduced by Drs. Ringer and Sainsbury, showing that even after the nerve terminations are paralysed by curara, a condition of muscles similar to that which occurs in Thomsen's disease may be produced by certain drugs. But, on the other hand, the symptoms in the case point to an alteration in the action of the motor cells of the cord. It must be remembered that these cells, even when the muscles are at rest, are still active, as the tone and the adjustment of the muscles must still be provided for. When the call to voluntary activity comes from the brain, this voluntary excitation subdues, as it were, this more or less automatic activity of cells, but in conditions like Thomsen's disease it may be supposed that this automatic activity persists temporarily, in spite of the will, yielding after a time; yet in the case described in this paper, the will was unable, even after a time, effectively to counteract the condition. The persistent condition of the muscles, the hardness and tenseness may conceivably be the result of prolonged disturbance of the action of nerve-cells, a view which receives support from the fact that Thomsen's disease sometimes shows itself in adults, and in most cases is slowly developed.'

NEW SYNTHESIS OF TARTARIC ACID.

SOME light on the natural formation of tartaric acid is afforded by the recent discovery of a simple way in which this acid may be synthesised. A French chemist, M. Genresse, starts with glyoxalic acid—an acid found in gooseberries, grapes, and other fruits—and acting upon it with nascent hydrogen liberated from a mixture of zinc dust and acetic acid obtains eventually tartaric acid, or rather the optically inactive form of it known as racemic acid, equal molecules of the dextro and lævo varieties being apparently produced. The explanation of the action is very simple. Two molecules of glyoxalic acid are merely brought together by two hydrogen atoms. Glyoxalic acid is $C_2H_2O_3$, while tartaric acid is $C_4H_6O_6$, a formula which, as will be readily seen, contains two molecules of the former acid joined together by two atoms of hydrogen. It is well known that oxalic acid, $C_2H_2O_4$, is formed most readily in vegetable tissues, and is closely related to glyoxalic acid. Having regard, therefore, to the reducing tendencies which are known to characterise chlorophyll, it is not improbable that the natural building up of tartaric acid may be thus explained.

COMPULSORY VACCINATION IN BOMBAY.

WE have already had occasion to notice the creditable tone of the discussion on the second reading of the Bill for securing compulsory vaccination in the Bombay Presidency, as it has long been secured in Bombay itself. The only difference which arose was on the part of those who think that some great risk lurks in arm-to-arm vaccination as involving the transmission of objectionable diseases. They objected to the clause which gives authority to the Governor-General in urgent circumstances, and, where animal lymph cannot be obtained without dangerous delay, to authorise the use of human lymph. The chief exponent of this objection was the Hon. Mr. Javerilal W. Yajnik. He was well answered by the Hon. Mr. J. R. Naylor and others, who declared that there had been no complaint of the action of human lymph. Mr. Naylor, in particular, said that in thirty years' experience of litigation and complaints of all sorts in the Mofussil no complaint of this kind had come within his knowledge. The Governor, however, and his colleagues had no difficulty in suggesting a modification of the clause, common to this Bill and the Bill of 1878, for Bombay itself, authorising the governor to sanction the use of human lymph with which Mr. Javerilal W. Yajnik expressed himself as quite satisfied. It had reference to the provision of regulations as to the source from which the lymph is to be obtained, and the means by which its purity is to be maintained. This little difference being adjusted, the adoption of this beneficent Bill was practically settled, and a lesson was given in reasonableness to less enlightened opponents of such legislation at home. While we are confident that the dangers of arm-to-arm vaccination are greatly exaggerated, it is interesting to note that in Bombay for fourteen or fifteen years it has been found practicable to conduct public compulsory vaccination with calf lymph alone.

THE DANGER OF COUNTER-IRRITATION IN LOCALISED TUBERCULOSIS.

ACCORDING to Parrachia Anacleto, counter-irritation in localised tuberculosis is attended with great danger. Miliary tuberculosis spreads so rapidly from one organ to another by way of the veins and lymphatics that any irritation set up at the seat of the primary mischief cannot fail to increase the tendency of the disease to become general. Four cases which have recently come under his notice show this in a remarkable degree. Tuberculosis progresses slowly, but it allows of no violent remedies, and, he thinks, until some method of treatment more successful than either the injection of tuberculin, or cantharidate of potash, or the application of blisters has been discovered, the danger of causing general infection by their adoption will still remain.

THE DOUBLE CYANIDE OF ZINC AND MERCURY.

PROFESSOR DUNSTAN has already shown that when a solution of zinc sulphate is added to a solution of mercuric potassic cyanide, or when mercuric chloride is added to a solution of zincic potassium cyanide, a white precipitate is formed, which does not consist, as stated, of a double cyanide of zinc and mercury of the formula $ZnHg(CN)_4$. Further experiments, an account of which was given by Prof. Dunstan at the meeting of the Chemical Society on the 17th ult., indicate that this precipitate is in many respects a remarkable substance. The quantity of mercuric cyanide retained is dependent on the amount of water present during precipitation, as well as on the proportion in which the salts interact; the maximum quantity retained is 38·5 per cent. Zinc cyanide, having this percentage of mercuric cyanide attached to it in such a form that it cannot be removed by ordinary washing with cold water, is precipitated when cold saturated solutions of the two salts are mixed in equimolecular proportions. A series of experiments, in which the masses of the interacting salts were varied, proved that a compound of the two cyanides is formed, and suffers decomposition to a greater or less extent, depending on the relative amount of water present. Examination led subsequently to the inference that the composition of the double salt is expressed by the formula $Zn_4Hg(CN)_{10}$. Such a salt contains 40·6 per cent. of mercuric cyanide. It cannot be obtained pure, since it is decomposed by water, and it can only be produced by precipitation of aqueous solutions. All attempts to prepare the double cyanide by methods other than that of precipitation have failed. There was no forthcoming evidence of the existence of any other compound of the two cyanides than that described, nor could any similar compound of zinc cyanide with other metallic cyanides than that of mercury be obtained. widely known now that this tetra-zincic monomercuridecacyanide has been found to be an admirable surgical antiseptic. Sir Joseph Lister, its introducer, who was present at the meeting, and at whose suggestion the inquiry was undertaken, said that the great value of the salt arose from the circumstance that, while equally effective as an antiseptic, it had none of the irritant qualities of mercuric cyanide, and its slight solubility was an advantage. When mercuric chloride was used it was liable, on the one hand, to be washed away by the discharges of a wound, and, on the other, to accumulate until a solution was formed which was so concentrated that it caused great irritation. He was glad that Professor Dunstan had come to the conclusion that it is a definite chemical compound, because he had not been satisfied from its behaviour that it could be a simple mixture.

STATE SURVEILLANCE OF FOOD IN ITALY.

WE have from time to time remarked on the energy and effect with which Italians are improving their public health laws in respect to which the sale and consumption of deleterious foods and drinks used to be quite a scandalous feature. Under the new sanitary code the risk to the consumer of such dangerous ingesta is becoming rapidly minimised, a fact which cannot but be reassuring to the travelling public, who pass so many of the winter and spring months in the peninsula. Of late years Milanese butter, justly valued for its purity and flavour, has offered a peculiarly tempting field to the adulterator. According to an official statement now before us, the public health officers, for some time on the watch for such malefactors, have come upon the source of an enormous supply of "burro falsificato," sold as genuine Milanese butter at home and abroad. Specimens of this, examined under the microscope with polarised light, have revealed the presence of margarine, whose characteristic crystalline structure was, even in the minutest quantities, put in evidence by this detective means, and this only. A notoriously common and at the same time subtle form of adulteration is thus placed within the immediate cognisance of the public analyst, and the Milanese journals are already congratulating themselves on a discovery which bids fair to rehabilitate the character of one of the chief Lombard industries which was fast becoming fatally compromised. It is to French, not to Italian, initiative, however, that this addition to the public health officer's armoury is due. It was M. Pennetier, of the Chemical Laboratory at Rouen, who devised the method of detecting margarised butter under the microscope by polarised light. But, be its origin what it may, the method has been promptly utilised by the health officers of Italy, to be followed up, we hope, by other and not less efficacious means of food protection in the interests of her own people and of the stranger within her gates.

ELIMINATION OF TOXINES IN ENTERIC FEVER.

MM. ROQUE and WEILL[1] have made some experiments for the purpose of studying the elimination of toxines in enteric fever. The toxic power of the urine is shown by its ability to kill animals when injected subcutaneously. The average quantity which is necessary to kill a rabbit of a given weight determines the normal uro-toxic coefficient. These observers, in their preliminary experiment, allowed a patient suffering from typhoid fever to remain entirely without treatment; they then found that the uro-toxic coefficient was doubled. This they considered to represent the unaided efforts of nature to expel the poison of this disease. That the quantity, however, is insufficient is shown by the fact that the toxicity of the urine remains above the normal for four or five weeks after the fever has abated. When patients are treated by the cold bath method the uro-toxic coefficient becomes greatly increased, attaining an amount equal to five or six times the normal. This increase lessens as the temperature falls and the general symptoms improve, and it falls to the normal at the same time as the fever. This would seem to indicate that the cold bath is a satisfactory treatment, producing elimination of the toxic products, and this agrees with the clinical observation of the success of this treatment in practice. Antipyrin, on the other hand, produces an opposite effect, and when it is employed the uro-toxic coefficient is diminished almost to that observed in health. Several explanations may be given of this action. The antipyrin may act as a direct antidote, preventing the formation of toxines, or it may prevent their excretion or postpone their formation. After the use of this drug the discharge of toxines is found to be enormously increased during the first week of convalescence. Further investigations will be necessary before it can be shown how far each of the above contingencies results from the use of the antipyrin. Teissier has made similar experiments to determine the action of naphthol, and his investigations show that this substance is a true antiseptic, preventing the production of toxic bodies both during disease and convalescence.

NEURASTHENIA AND HYPER-ACIDITY.

THE *Medicinisch-Chirurgische Rundschau* reviews an article by A. Pfannenstill of Stockholm in the *Nordiskt Med. Ark.* on the connexion between the above-named two conditions. Neurasthenia and nervous dyspepsia are, according to the writer, as frequently seen in Sweden as in other parts of the world. A valuable addition to the etiology of these complaints is that all the cases observed by Pfannenstill belonged to the working classes, so that neurasthenia is certainly not confined to the upper classes of society, who are most exposed to the excitement of modern life. Of both complaints a primary and secondary form can be distinguished; but the latter, which is merely a symptom of other affections, especially hysteria, is much the more frequent. Hysteria is more often observed in connexion with a general neurasthenia, in which the functions of the secreting nerves are always disturbed, and we may find in consequence hyper-acidity and hyper-secretion, or subnormal acidity, or even an entire absence of acid. The hyper-acidity is entirely due to an increase of hydrochloric acid. Pfannenstill considers that this hyper-acidity is the result of an increase in the quantity of the gastric juice, and not merely of the hydrochloric acid, and that there is no decrease in the power of absorption. Increased secretion of gastric juice is probably the source of hyper-acidity in other affections of the stomach, and the reverse is probably equally true.

THE SECRETION OF UROBILIN IN CERTAIN DISEASES.

G. HOPPE-SEYLER, assistant in the medical clinic of Professor Quincke at Kiel, publishes in Virchow's *Archiv* some observations on the secretion of urobilin. If urobilin is dissolved in a solution of caustic soda and a small quantity of calomel added, the yellow solution assumes a beautiful rose-red colour. If the solution is then filtered to remove the oxide of mercury, and, after the addition of hydrochloric acid, shaken up with amyl-alcohol, a solution of the red pigment is obtained, which has the same chemical reaction as a solution of urorosein, described some time ago by Nencki and Sieber. Hoppe-Seyler concludes from this fact that urorosein is produced in the same way by the oxidation of urobilin in the system. After a series of analytical experiments he finds that an increase of urobilin in the urine takes place in retention of bile with plentiful diuresis

Digitized by Google

or when bile still finds its way into the intestine, as in polycholia. The same increase takes place in constipation affecting the large bowel, but not in the case of the small. It is also found in hæmorrhage into internal organs. A fairly normal quantity was found in cases of pernicious anæmia, leukæmia, and pseudo-leukæmia, but a decrease was observed in various cachexiæ, general debility, and in some cases of anæmia as well as in congestion of the liver with arrest of biliary secretion and an absence of diuresis.

FOREIGN UNIVERSITY INTELLIGENCE.

Berlin.—It has been announced that Professor Krause of Göttingen has been appointed to the chair of Pathological Anatomy, but there appears to be some doubt about this appointment. Dr. Karl Moell, Director of the Asylum at Dalldorf, has been granted the position of Extraordinary Professor.

Berne.—Professor Drechsel of Leipsic has been offered the chair of Medical Chemistry, vacated by Professor Nencki, who is going to St. Petersburg.

Gratz.—For the chair of Dermatology the three names sent up by the Professorial Senate are (1) Professor Jarisch of Innsbruck and (2) Drs. Finger and Riehl (who obtained an equal number of votes), both of Vienna.

Vienna.—Professor Kahler has been obliged to obtain leave of absence on account of his health.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.

THE deaths of the following distinguished members of the medical profession abroad have been announced:—Dr. Anton Karsch, Professor of Natural History in the Academy of Münster. He was the author of works on zoology, insects, the flora of Germany and of Westphalia, and of numerous pamphlets on educational questions viewed from a political point.—Professor Karl Saur, who contributed largely to the scientific education of dentists in Berlin, having written on surgery, with special reference to the teeth and jaws, and taught until some four years ago in the Dental Institute.—Dr. Steenberg, Professor of Mental Diseases in Copenhagen.—Dr. Armand de Fleury, Professor of Therapeutics in Bordeaux.—Dr. Barthélemy, Director of the Naval Medical Service at Toulon.—Dr. Victor von Ivanchich, formerly a distinguished operator, at the age of eighty, at Vienna.

PALERMO will be the seat of the next Congresso della Federazione delle Società Italiane di Igiene, which will be held from the 16th to the 20th of May. The organising committee have announced the following special subjects in the programme:—1. On prostitution in relation to existing regulations. 2. On the drainage of seaports. 3. On the hygiene of sulphur mines. 4. On the sanitary inspection of schools.

DR. B. W. RICHARDSON, F.R.C.P., F.R.S., has been appointed physician to the London Temperance Hospital, in the room of Dr. James Edmunds, resigned. The Board at the same time appointed Dr. John Fletcher Little, M.R.C.P., an assistant physician.

THOMAS HUGH DICKSON, M.A., M.B., B.C. Cantab., M.R.C.S. Eng., L.R.C.P. Lond., has been appointed Medical Inspector in Her Majesty's Customs, vice Walter Dickson, M.D., R.N., retired by seniority.

GENERAL PRACTITIONERS' ALLIANCE.—We are informed that the meeting of the members of the General Practitioners' Alliance, to consider the draft charter of the Royal British Nurses' Association, will be held at Exeter Hall on Tuesday next, April 5th, at 4 P.M., and not on the 12th, as previously announced.

Pharmacology and Therapeutics.

PARACRESOL AS A DISINFECTANT.

PARACRESOL obtained by Quiriny from wood tar is a more powerful disinfectant than either bromine, chlorine, or cresol. It is soluble in all proportions in water, giving clear, neutral, and almost inodorous solutions. As an antiseptic it is more energetic than carbolic acid, a 5 per cent. solution killing the bacteria of anthrax in ten minutes. An aqueous solution, with a small quantity of glycerine, makes a good wash for the skin in measles and scarlatina, and is especially recommended for use among midwives.

VESICATION BY MEANS OF A SOLUTION OF CORROSIVE SUBLIMATE.

M. Aubert of Lyons publishes an account of a new method of producing vesication. A compress of lint soaked in a solution of sublimate of the strength of 1 to 100 and applied to the skin produces in six or seven hours a blister similar to that produced by cantharides. This blister is of the exact size and shape of the compress, and the serum is said to be aseptic. In applying this method the neighbouring skin must be protected by strapping, and the compress held in its place by a bandage. M. Aubert has made use of this form of blistering in syphilitic acne with good results.

ATROPINE AS A HÆMOSTATIC.

In two cases of profuse metrorrhagia A. N. Dimitrieff has obtained good results by the subcutaneous injection of atropine in doses of 0·0003 gramme. In the first case the hæmorrhage stopped after four injections; in the second after three. Atropine is sometimes of service when other hæmostatics have failed. Dr. Dimitrieff is unable to explain the action of atropine, but it is certain it affects the blood pressure; but whether by acting on the vaso-motor nerves or on the vessels themselves, or on the vaso-motor centre, is, he considers, doubtful.

THE USE OF CORNUTIN IN HÆMORRHAGE FROM THE GENITO URINARY ORGANS.

A. Meisels, after satisfying himself as to the truth of Kobert's assertions that ergotinic and sclerotinic acids possess vaso-dilator properties, and that sphacelinic acid and cornutin cause contraction of muscular tissue, has treated urethral, vesical, and uterine hæmorrhage with pure cornutin; 0·01 gramme was given daily in divided doses. The results were very satisfactory.

SALOPHENE.

Salophene occurs in small white flakes almost insoluble in water, very soluble in alkaline solutions, in alcohol and ether. Its solution in alcohol is turned violet by perchloride of iron, and gives a bulky white precipitate with bromine water. It is quite tasteless and inodorous, and melts at 187° to 188° C. Alkalies break it up into salicylic acid and acetylparamidophenol. The same change takes place in the body when it comes into contact with the pancreatic or intestinal fluid. It passes unchanged through the stomach. According to the researches of W. Siebel, 88 per cent. is decomposed if given in doses of 2 grammes, but only 69 per cent. if given in doses of from 5 to 6 grammes; thus there is no advantage to be gained by giving more than 5 or 6 grammes during the day. The salophene not decomposed is eliminated by the bowel. The acetylamido-paraphenol is partly excreted by the kidneys, and the salicylic acid can be found in the urine fifty hours after the administration of the drug. Salophene is much less poisonous than salol, the lethal dose for a rabbit being from 7 to 8 grammes, death being caused by the presence of salicylic acid. Siebel comes to the conclusion that salophene is superior to salol, both on account of its want of taste and smell, as well as from its less poisonous properties.

THE EMPLOYMENT OF SICCATIVE LINIMENTS IN SKIN DISEASE.

The *Prager Medicinische Wochenschrift* publishes a communication from Professor Pick of Prague on the use of these liniments. He complains that in the usual formulæ the remedy does not come sufficiently into contact with the skin. To obviate this defect he has made use of bassorin, a constituent of gum tragacanth, prepared in the following manner:—Gum tragacanth, 5 parts; glycerine, 2 parts; water,

two exceptions the methods and apparatus employed are very imperfect. In France, where disinfection is not obligatory, where it is often neglected, it will be found that, on the rare occasions when it is employed, it is managed in a more scientific and thorough manner than is generally the practice in England. For instance, while in England many sanitary authorities are content to expose contaminated bedding and clothes in a clumsy sort of stove where dry heat only is produced, and this rarely to more than 220° F., all the disinfecting stoves in France are filled with superheated steam under pressure, and great care is taken that the intensity of heat is equal in every part of the apparatus. Under such circumstances disinfection is much more reliable, and can be more rapidly applied. It was the improved methods of disinfection which the French delegates submitted to the Venice Conference, and these improvements rendered what seemed at first an impracticable suggestion comparatively easy to carry out.

Ships coming through the Suez Canal will be, we are told, classified in three categories. There will be, first of all, ships about which nothing can be said, no shadow of suspicion resting upon them. Such ships will pass through the canal without let or hindrance. The second category will consist of ships that have sailed from a port where cholera is known to prevail, even though there may not be any case of cholera for seven days previously to the departure of the ship. This category is to be qualified as that of the "suspects." These suspected vessels, which, according to the old methods, would have been placed in quarantine, will simply be disinfected. Very powerful and large disinfecting stoves are to be established, and bedding and personal apparel will be promptly purified by exposure to superheated steam under pressure. The English delegates suggested as an amendment to this proposal that mail ships, if they carried on board disinfecting stoves, should be exempted. This amendment was accepted on the double condition that the disinfecting stove carried on board must be of an approved pattern, and that the ship's surgeon must be appointed by Government. The surgeon would have to guarantee the perfect salubrity of the ship, or else supervise the thorough disinfection of all that was on board and likely to be contaminated. These conditions were accepted, and it was even suggested that other vessels besides the mail ships might be allowed to pass straight through the canal if there was good reason to believe that the doctor in each case would cause everything to be properly disinfected before reaching Suez. The English delegates made one more stipulation—namely, that in the case of troopships, only that portion of the ship occupied by troops coming from a contaminated port should be disinfected. The third category consists of contaminated ships—namely, ships on which cases of cholera have occurred during the voyage. In that case the disinfection practised will be much more rigorous, and will require longer time. Still the delay is never to exceed five days, and generally it will be less than this. Such possible delay of five days may seem somewhat alarming; but if the future may be judged by the past, it is not likely to make any practical difference with regard to the rapidity of our communications or the facilities of our commerce. According to a calculation made at the conference, it was found that during the last seven years only three English ships would have been placed in the third category. The French delegates thereupon were able to urge with much success that it was better to stop for a short time one ship every two years than to run the risk of contaminating the Mediterranean with so fearful and dangerous a scourge as that of cholera.

To carry out all these regulations it was proposed to establish a Sanitary Department at Suez, and to modify the Sanitary Council of Alexandria. Four medical men will be permanently on duty at Suez. They will constitute the executive of the Alexandria Committee, and will decide whether the ships arriving at Suez have fulfilled the above stipulations and can be allowed to pass through the canal. The Sanitary Committee is to be reduced from twenty to seventeen members; but, on the other hand, there will be an increased expenditure for the maintenance of the medical men at Suez, for the disinfecting services, &c. This is to be met by a tax of 10*d.* on each passenger going through the canal, but soldiers and functionaries are to be exempted. Then there will be a very slight increase on the tonnage dues for ships going through; and finally, there is a surplus balance resulting from the tax raised for the maintenance of the lighthouses. All these sources of income will amply suffice to produce the £6400 per annum which it is estimated the new services will cost.

The French delegates to the Venice Conference are unanimous in recognising the readiness with which the English representatives took in hand the French proposals and studied them in a manner which conclusively proved how strong was their desire to come to a common understanding. The *Journal des Debats* and other important organs of public opinion in France have expressed much satisfaction with the Venice Conference. If all international negotiations were dominated by the same spirit as that which prevailed among the sanitary reformers who met at Venice, it would be very difficult indeed for any international misunderstanding or quarrel to arise. It is urged, therefore, that the Venice Conference should be taken as a model; and we are not a little gratified to find that medical men have succeeded in giving so good an example to the diplomates of all countries.

On one or two points the English delegates found themselves in a very small minority. There were fourteen powers represented at the Venice Conference. The English proposed that even contaminated vessels should be allowed to pass through the Suez Canal on condition that they displayed the quarantine flag, that they had no communication whatsoever with the shore, and that they were bound direct to an English port. This proposal was defeated by ten votes against four, the representatives of the Triple Alliance alone voting for the English proposal. The English delegates were also opposed to the reduction in the number of members of the Alexandria Sanitary Committee. This reduction from twenty-two to seventeen members was to be effected by nominating only four instead of nine Egyptian Commissioners; but, as the Egyptian Commissioners are in reality appointed by the English, the proposed alteration will practically result in imparting to the Alexandria Sanitary Committee a more international character. This international character was marred by the exaggerated predominance of English influence. To these arguments the English delegates refused to assent, and, the matter being brought to a division, twelve nationalities voted in favour of the proposal and two against. The German representatives alone voted with the English. Consequently, the Alexandria Sanitary Committee is to be reduced from twenty-two to seventeen members by curtailing the number of Egyptian representatives from nine to four. Out of the fourteen nationalities represented the delegates of ten nationalities at once signed the agreement, but the delegates of England, Denmark, Belgium, and Turkey desired to refer the matter to their respective Governments. Since then Denmark and Belgium have sent in their approval; the signatures of England and Turkey alone are wanting.

There is one point on which the attitude of the French is somewhat inconsistent. Dr. Proust and Dr. Brouardel showed that they were imbued with modern ideas, and proclaimed their faith in sanitary measures and disinfection instead of quarantines. But in France the only statute that exists on this subject is the statute or *règlement* of 1876, which most emphatically establishes quarantines. The French sanitary authorities, acting under the enlightened guidance of Dr. Proust and Dr. Brouardel, may not apply these old regulations, but still they exist; and it would make the French position stronger with regard to Suez Canal negotiations if they were abolished. An English ship may satisfy the sanitary authorities at Suez, and yet find itself placed in quarantine on reaching Marseilles. Have we a sufficient guarantee that the methods of protection approved by the French sanitary authorities as applicable at Suez would be also applied at Marseilles? This is, of course, quite a secondary question. Our great interest is with the Suez Canal and not with the French ports. Nor are the French alone inconsistent in this matter. Other nations would resort to quarantine in their own waters, though they seemed quite satisfied with disinfection and medical inspection at the Suez Canal. The fact that at the great international sanitary station of Suez more enlightened views are to be enforced will serve as an object lesson to all countries, and doubtless the French and other nations will soon follow this example. The decisions of the Venice Conference are undoubtedly a very great advance on the opinions entertained by most continental Powers with respect to quarantines, and as such should be heartily welcome.

sources of income will amply suffice to produce the
per annum which it is estimated the new scheme
cost.

The French delegates to the Venice Conference
unanimous in recognising the readiness with which
English representatives took in hand the French
and studied them in a manner which conclusively
how strong was their desire to come to a common
standing. The *Journal des Debats* and other more
organs of public opinion in France have expressed
satisfaction with the Venice Conference. If the
national negotiations were dominated by the same
as that which prevailed among the sanitary reformers
met at Venice, it would be very difficult indeed for
international misunderstanding or quarrel to arise.
urged, therefore, that the Venice Conference should
taken as a model; and we are not a little gratified
that medical men have succeeded in giving a good
example to the diplomates of all countries.

On one or two points the English delegates found
selves in a very small minority. There were two
powers represented at the Venice Conference. The Italian
proposed that even contaminated vessels should be allowed
to pass through the Suez Canal on condition that they
played the quarantine flag, that they had no communication
whatsoever with the shore, and that they were towed direct
to an English port. This proposal was defeated by
votes against four, the representatives of the Triple
Alliance alone voting for the English proposal.
English delegates were also opposed to the reduction
in the number of members of the Alexandria Sanitary
Committee. This reduction from twenty-two to seventeen
members was to be effected by nominating only four out
of nine Egyptian Commissioners; but, as the Egyptian
Commissioners are in reality appointed by the English
proposed alteration will practically result in increasing
the Alexandria Sanitary Committee a more international
character. This international character was marred by the
exaggerated predominance of English influence. In the
arguments the English delegates refused to assent, the
matter being brought to a division, twelve nationalities
voted in favour of the proposal and two against it.
German representatives alone voted with the English.
Consequently, the Alexandria Sanitary Committee will
be reduced from twenty-two to seventeen members,
curtailing the number of Egyptian representatives from
nine to four. Out of the fourteen nationalities represented
the delegates of ten nationalities at once signed the agreement,
but the delegates of England, Denmark, Belgium,
Turkey desired to refer the matter to their respective
Governments. Since then Denmark and Belgium
Governments. Since then Denmark and England
sent in their approval; the signatures of England
Turkey alone are wanting.

There is one point on which the attitude of the English
somewhat inconsistent. Dr. Proust and Dr. Brouardel
showed that they were imbued with modern ideas,
proclaimed their faith in sanitary measures and declared
instead of quarantines. But in France the only sanitary
that exists on this subject is the statute or regulation
1876, which most emphatically establishes quarantine.
The French sanitary authorities, acting under the
lightened guidance of Dr. Proust and Dr. Brouardel,
not apply these old regulations, but still they exist, and
would make the French position stronger with regard
Suez Canal negotiations if they were abolished. As the
ship may satisfy the sanitary authorities at Suez that
find itself placed in quarantine on reaching Marseilles.
Have we a sufficient guarantee that the methods of
tection approved by the French sanitary authorities
applicable at Suez would be also applied at Marseilles?
This is, of course, quite a secondary question. The
interest is with the Suez Canal and not with the French ports.
Nor are the French alone inconsistent in this matter. Other
nations would resort to quarantine in their own ports
though they seemed quite satisfied with dispensing with
medical inspection at the Suez Canal. The first thing a
great international sanitary station of Suez must organise
views are to be enforced will serve as an object lesson to
countries, and doubtless the French and other powers
soon follow this example. The decisions of the Venice
Conference are undoubtedly a very great advance on the
opinions entertained by most continental Powers
to quarantines, and as such should be hailed

POISONOUS CIGARETTES.

INTELLIGENCE of a startling kind not unfrequently comes from the United States, and that recently to hand will no doubt create some amount of alarm in the now wide circle of cigarette smokers. It appears that the Congress of the States is being urged to suppress the cigarette by taxing it at the rate of 10 dols. per 1000. The promoters of the measure state that cuttings taken from the newspapers throughout the States show that during the past year there have been about 100 deaths of young men, mostly under sixteen years of age, from the effects of smoking paper-wrapped cigarettes. In some cases, it is averred, an analysis of the contents of the stomach has been made, and in most instances there have been found phosphorus and arsenic, the latter being a substance, it is said, largely used in the manufacture of cigarette paper. About a hundred men, the report further goes on to say, have been consigned to "insane (*sic*) asylums" from the same cause. Meanwhile the Legislature of Ontario has just read a second time a Bill introduced by the Premier, prohibiting the use of cigarettes by anyone under the age of eighteen. Under this Act the penalty for smoking will be a fine of from one dollar to five dollars, while those who sell cigarettes to persons under eighteen will be fined from ten to fifty dollars. Whether it be a matter for legislation or not, it will be generally conceded that the growth of the habit of smoking amongst mere juveniles is a thing to be deplored. It is a matter of everyday observation now that boys of from even twelve to, say, eighteen years of age indulge in what is rightly regarded as a habit decidedly injurious to those who have not reached maturity. We are, however, strongly inclined to doubt whether the paper of the cigarettes referred to above contained any arsenic or phosphorus. Such a paper, if it contained phosphorus in the elementary condition, and in quantity to be injurious, would impart a twang to the palate of the smoker which we imagine would hardly be relished. Moreover, phosphorus is a very unstable body, and in contact with air would rapidly change into oxidised products, which are highly deliquescent, considerably less poisonous, and if present in large quantity would render the paper quite wet. Why arsenic should be required in the preparation of cigarette paper we are equally at a loss to imagine. The very best material for this purpose need consist of nothing but the purest rice paper. A few years ago stories were in circulation in this country in regard to the noxious effects produced by the smoking of Egyptian cigarettes said to contain foreign substances, and the matter was considered sufficiently important to merit experimental inquiry. This was undertaken by our Analytical Sanitary Commission, the report of which is to be found in THE LANCET of Oct. 20th, 1888, p. 785. Summing up the results of our investigation, we reported as follows:—"The cigarettes which we examined were made from genuine tobacco. No foreign substance, and particularly no opium or other alkaloid, was added. The paper and the cement were pure, the only possible objection being the trace of copper found in the ash, which is probably due to the metallic lettering." The several samples then selected, though Egyptian, were regarded as fairly representative. If it be true that the paper used as wrappers for cigarettes in the United States are treated with, and contain, phosphorus and arsenic, the remedy is an easy one. Such procedure in the preparation of cigarettes should of course be prohibited; and just as articles of food are condemned in this country if they contain substances injurious to health, so should cigarettes containing any substance of a foreign nature be not only condemned, but seized and destroyed. The detection of both arsenic and phosphorus is a simple matter, which every analyst can perform; indeed, free phosphorus could be detected by anybody, since the cigarette paper containing it would glow in the dark. But we must confess an inclination to doubt whether either of these substances has actually been found in the articles in question. Should any members of the profession have occasion to suspect cigarettes to contain objectionable substances like those indicated, we should be glad to submit them to our analytical staff for examination, and, as on a previous occasion, to duly report the results in our columns.

THE MANUFACTURE OF BLEACHING POWDER AND WHITE LEAD.

THE SUFFERINGS OF WORKERS ENGAGED THEREIN.

THE task of the recently constituted Labour Commission is a heavy one, and it is to be hoped that it will be crowned by results which will materially assist in not only improving the condition of the labour market, but also in reducing the hardships and trials of many an honest labourer. Not the least important result of the inquiry must be an awakening of the community at large to the fact that in many trades the conditions under which the men work are far from healthy, and in many instances positively injurious, tending to shorten the life of the unfortunate *employés*. Already many startling statements have been made by witnesses in the Miscellaneous Trades Section, under the presidency of Mr. Mundella. The secretary of the National Amalgamated Society of Coopers, Newcastle-on-Tyne, for instance, gave evidence on March 18th concerning the conditions of labour in various chemical works. Respecting the manufacture of bleaching powder, he said that the conditions of work in factories where the heading-up of casks of bleaching powder is carried on are very unsatisfactory. This work is done in large chambers, and after the cask is filled with material the end has to be put in and fixed so that the bleaching powder shall retain as much gas as possible. In order to avoid the injurious effect of the gas given off by the powder the men have to wear a flannel muzzle. The muzzle, it was stated, is put over a man's mouth and nostrils and tied tight round; it was used by the chemical workers themselves as well as by the coopers. The men dropped down in these packing chambers, even with the muzzles on, overcome by the deadly gas. They were able, when wearing the muzzle, to breathe a little through the nostrils, but they were supposed to breathe through the folds of flannel to avoid the gas as much as possible. The nostrils had to be saturated with oil, and the oil was put on round their eyes and eyelashes and other exposed parts. They worked an hour at a time, and then came out to get fresh air. In their Society was one man who was suffering through inhaling gas under these conditions, and he (the witness) did not know whether he was alive at the present moment. The men got 6*d.* a ton for this work; so that, if a cask held 5 cwt., they would have to head up four to earn 6*d.* They worked fifty-three hours a week, and were often called upon in the night. The detrimental effect of the gas shows itself in the respiration of the men. A man has sometimes been noticed to scarcely breathe, and if anyone has been indulging in smoking the witness has seen them compelled to hold their handkerchiefs over their mouths; they are afraid to inhale any tobacco smoke, because it gives them a severe fit of coughing. In many places he had never seen an inspector, though he had heard of an inspector visiting them. They always knew when an inspector was coming, because the factory was always cleaned up, which indicated that notice of his visit had been given. In the bleaching-powder factories the lime for the powder was laid down about five inches thick in a large chamber. The doors were then sealed up and the chlorine-gas was put into the room, which were left sealed until such time as the lime absorbed the chlorine. Then the men, wearing muzzles such as had been described, went into the chambers and put the bleaching powder down through the shoots underneath, where there were casks to receive it. In addition to this muzzle they had to wear goggles over their eyes, and then on any portion of the skin that was exposed they had to put tallow or grease. Most of these men could not eat any food until they took a stimulant, such as whisky or rum. The men in all the yards were liable to be "gased." As an instance of this, there were two works in St. Helens—one known as the Sutton Lodge and the other as Kurtz's. Sutton Lodge was about 500 yards distant from Kurtz's, but the men in Kurtz's had had to run for their lives when the gas came over in large volumes from Sutton Lodge as the chamber doors were opened. One of them had seen a horse fall down in consequence of getting "gased" in Kurtz's yard. The works were divided into a bleaching-powder department, a vitriol department, a black-ash department, a salt-cake department, a caustic department, and a chlorate department.

Digitized by Google

The bleaching department was the most dangerous. The men at the salt-cake department had to keep what they call a rag in their mouths, through which they breathe, and the teeth of these men are generally black and worn down to the gums. Every man inside a chemical works is likely to get gased—in fact, those living outside a works get afflicted more readily with bronchitis than people living in other districts, owing to the proximity of the factory. The men employed in this industry suffered more generally from disease than men in other industries, and he did not believe they lived so long.

The men in the white-lead factories were subject to the poisonous effects of the lead. They had to head-up casks in a way similar to that adopted in the bleaching factories. While they were knocking in the covering of the cask they were involved in white-lead dust, which they inhaled. He had known some of the members of their Society suffer from twisted joints from the action of the lead in the system. Lead poisoning was quite a common occurrence with the workers, and with young people especially. He had seen comparatively young women with their hands so that they could not take the pay when it has been put upon the table—they could not pick it up, and they had to wipe it off the table; they had not the power to pick anything up. He thought greater precaution might be taken than was at present done, and that it would be well if the inspector would not notify the employers when he was coming, so that he could see the operatives working under ordinary conditions. It might be possible to have a shoot in the "ovens," and the white lead might be put into the shoot, and so come direct into the cask. If that were done, it would remove nine-tenths of the difficulty that was caused now.

These are a few facts culled from the enormous mass of evidence which lies at the disposal of the members of the Commission, and we can only express the hope that instances of even a worse kind will not be forthcoming.

HUMPHREYS' PATENT IRON HOSPITALS AND OTHER BUILDINGS.

IT is probable that our readers are already acquainted with these structures, but in case they are not we desire to call attention to them, because the system admits of their being furnished of all sizes and capable of fulfilling a variety of purposes and requirements in everyday life. The designs are for iron churches, chapels, schools, hospitals, cottages, bungalows, offices, barracks, canteens, station buildings, workshops, &c. The buildings are of corrugated galvanised iron, lined with match-board, with a padding of felt between the two, and the construction admits of their enlargment when necessary. They are stated to be warm in winter and cool in summer, and are consequently adapted to all kinds of climates. The windows and doors can be supplied according to requirements, together with such an amount of ridge and other ventilation as may be deemed necessary. The wall framings are constructed of timber, morticed and tenoned, not spiked, so as to be easily taken down and re-erected. The interior is supplied throughout with match-boarding. The flooring is of planed boards one inch thick. The whole of the roofs, gables, and walls are lined throughout with felt, allowing an air space between match-boarding, purlins, and iron. The foundation required is of about two- to four-course brickwork, a ground plan of which is supplied to the local bricklayer. These buildings can be very quickly put up, and, as we have said, are of almost any size and character, and are said to last thirty or forty years. They can of course be fitted as required with stoves for warming, hot-water apparatus, bath and lavatory, and other offices. We think them well adapted for small hospitals for the isolation of infectious and other diseases, as well as for numerous other purposes that may be easily imagined, and they have the merit of being cheap. We would counsel anyone requiring any structure of the kind to visit the works at Knightsbridge and inspect some of those on view and the plans of buildings of various kinds.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Torquay Urban District.—Mr. Karkeek has before pointed out that increase of population in Torquay can hardly be expected; its area is limited, it is becoming more and more reserved for business purposes, whilst residences are being erected in the outside suburbs. Indeed, the population has only increased by 757 during the past decennium. The death-rate on over 25,000 people was 13·8 per 1000 last year, and it included some diphtheria deaths. This disease is believed to have been absent from Torquay for many years, and it certainly has not existed there in a fatal form; but under meteorological conditions involving much dampness and depression of vital powers the disease prevailed off and on, causing eleven attacks spread over the greater part of the year. Improvement is going on as to the housing of the working classes, and houses that are found unfit for human habitation are being closed.

Millom Urban District.—The death-rate for this district was 14·6 per 1000 during 1891, and Mr. Butler Stoney shows that little of the mortality was due to zymotic causes. The general health of the district is stated to show improvement, and this change is going hand-in-hand with the substitution of waterclosets for the old midden privies. The work in this direction is, however, by no means finished, for it is reported that no less than 8169 middens were emptied during the year. So long as those structures which cause nuisance and tend to ill-health are, in the first instance, dealt with, the local authority will probably find enough to do, and the effect will be one beneficial to the individual occupiers and to the district generally.

Caxton and St. Neots Districts.—The water-supply question for the villages is difficult of solution; the existing arrangements are bad, and it is feared that such amendment as would really be satisfactory would involve an expenditure that could not well be borne. The town of St. Neots suffers in a similar way, and unless the authority soon get a proper supply from the East Huntingdon Waterworks Company, they should proceed with another scheme. In the three districts combined the death-rate for 1891 is calculated by Mr. Poyntz Wright as high as 17·9 per 1000; but this was largely due to pulmonary diseases. The need for an isolation hospital is again put forward in the report, which contains an excellent statistical appendix.

Maldon Rural District.—Dr. Thresh has issued a very complete report on the sanitary circumstances of this district. It includes a reference to its shortcomings, but, on the other hand, it tells of substantial progress, such as an attempt to get better water for Southminster, the preparation of plans for the sewerage of Tolleshunt D'Arcy, and systematic inquiry into the condition of the dwellings of the poorer classes. One evil referred to as regards the latter is the damp brick flooring on which children crawl about, to the danger of their lives from pulmonary and other diseases. To a large extent the district is supplied with privies, and elsewhere hand-flushed closets are in use. These latter are found to be objectionable, and it may turn out that where sewers are available automatically flushed sink-waterclosets may meet the difficulty. Dr. Thresh has more than once referred to a connexion between London manure and diphtheria, and he gives further information in this report as to the same apparent connexion in the case of an outbreak at Tolleshunt D'Arcy. The death-rate from all causes was 15·1 per 1000 for 1881-90, and it was 16·3 last year.

Stretford Urban District.—According to the last census, the death-rate during 1891 was 17·5 per 1000 living, and the zymotic rate 2·0 per 1000 Under the notification system 81 cases were reported, 41 being scarlet fever, 21 enteric fever, and 15 diphtheria. Isolation is carried out, and in the case of houses under £20 rental per annum no charge is made for the use of the fever hospital. This, it may be hoped, is a first step towards free admission into a building purchased and maintained at the cost of all the ratepayers, whether living in cheap or more expensive houses. Mr. W. Healop gives a general account of the different sanitary circumstances of the district, and of the action taken during the year. He regrets the delay in re-sewering the district,

and he gives details as to a number of amendments which have been carried out.

Sutton Coldfield Urban District.—In dealing with zymotic diseases in this district, Dr. Bostock Hill refers to an outbreak of scarlet fever which was associated with the use of a special milk-supply. The case has already been brought before the Society of Medical Officers of Health, and we need only here refer to it in connexion with the proof afforded of the relationship between the disease and the milk, and of a relationship of the occurrence with a diseased condition in one of the milch cows in the dairy in question. Eruption and sore on the udder, coat rough and staring, raised temperature of body, hairless patches, &c., recall to mind the condition of cows in the Hendon case, as also does the veterinary certificate, to the effect that the cows were healthy. This latter is dealt with by Dr. Hill, who maintains that judgment as to healthiness in a cow should not be formed on the question whether they "eat well and milk well." Many a convalescing case of scarlet fever in a mother might come under the same description and yet be highly infectious. The report also deals fully with the sanitary state and requirements of the district; and the general death-rate for 1892 is given as 18·60 per 1000, the chief cause of the excessive mortality being the influenza epidemic.

West Hartlepool Urban District.—Dr. S. Gourley appends to his report a very useful chart indicating the localities in which cases of the various infectious fevers have occurred; the zymotic rate was 2·0, most of the fatality being due to diseases especially affecting childhood, such as whooping-cough and diarrhœa, and in this connexion it is pointed out that half the total deaths occurring at all ages were in children who had not yet reached five years of age, a matter calling loudly for immediate measures of prevention. Some substantial but much-needed repair of sewers has been carried out. The scavenging is fairly done, but would, as in most cases, be more efficient if done by the authority rather than by a contractor, and the water-supply is good. The general death-rate for 1891 was 17·2 per 1000.

Hartlepool Rural District.—Here Dr. Gourley reports a death-rate of 18·0 per 1000 living, but the zymotic rate was only 1·3. Notification favoured the prevention of scarlet-fever and diphtheria by facilitating early measures of isolation and school closure. Care is taken to look after the cow-byres, but although improvements have been effected, further measures are still called for. One important requirement, so often prominent in rural districts, calls for attention. It relates to the need of rain-spouting, a matter to which Dr. Gourley rightly calls attention; for the absence of it leads to saturation of subsoil and foundations with wet, and is often associated with the excessive incidence of pulmonary consumption.

Scarborough Rural District.—This district had a general death-rate of 15·9 per 1000 last year, and in referring to this Dr. Cuff discusses the question of influenza and its effect on the death-rate. His experience is that the period of incubation varies from a very brief one to five or six days, and that the disease is infectious during the first twenty-four hours. The infectious diseases that prevailed are considered in connexion with their causation, and a description is given of the general sanitary circumstances of the district. Water-supply is especially referred to, and it is satisfactory to note that services from extraneous sources are being delivered to villages and populous places. The houses of the working classes are also looked to, and instances are given in which overcrowding has been abated.

Hastings Urban District.—This seaside resort had a population of 52,223 at the last census, and the death-rate last year was 16·9 per 1000, the increase over the mean being due to pulmonary diseases following on influenza and severe weather. The increase in diphtheria fatality is very serious. The average number of deaths per annum during the previous ten years from this cause was 4·8, but no less than 23 such deaths occurred last year, and, so far as cause is concerned, the report merely says that most cases were apparently due to defects in domestic sanitation, an experience which by no means clears up the real point at issue. Indeed, the whole subject of this serious fatality is, after reference to some previous report, dismissed in a few lines. Improvements are stated by Dr. Scarlyn Wilson to have been carried out at the iron isolation hospital, where fifty persons were isolated; and it is added that, out of 210 cases of scarlet fever received into the hospital during the past four years, no single case has terminated fatally.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In thirty-three of the largest English towns 5995 births and 4348 deaths were registered during the week ending March 26th. The annual rate of mortality in these towns, which had increased in the preceding three weeks from 20·5 to 24·8 per 1000, declined to 22·3 last week. In London the rate was 28·3 per 1000, while it averaged 22·9 in the thirty-two provincial towns. The lowest rates in these towns were 9·9 in Brighton, 12·8 in Croydon, 13·6 in Derby, and 16·3 in Hull; the highest rates were 29·6 in Preston, 31·0 in Halifax, 35·0 in Oldham, and 37·2 in Huddersfield. The 4348 deaths included 435 which were referred to the principal zymotic diseases, against numbers increasing from 390 to 477 in the preceding three weeks; of these, 192 resulted from whooping-cough, 120 from measles, 48 from diphtheria, 32 from diarrhœa, 27 from scarlet fever, 16 from "fever" (principally enteric), and not one from small-pox. No fatal case of any of these diseases was registered in Plymouth; in the other towns they caused the lowest rates in Brighton, Croydon, and Preston, and the highest rates in Norwich, Salford, Sheffield, Bolton, and Wolverhampton. The greatest mortality from measles occurred in Liverpool, Sheffield, and Birkenhead; from scarlet fever in Cardiff; and from whooping-cough in Burnley, Sheffield, Bristol, Blackburn, Wolverhampton, and Bolton. The mortality from "fever" showed no marked excess in any of the thirty-three large towns. The 48 deaths from diphtheria included 30 in London, 3 in Manchester, 3 in Sheffield, and 2 each in West Ham, Birmingham, and Salford. No death from small-pox was registered either in London or in any other of the thirty-three towns; 35 cases of this disease were, however, under treatment in the Metropolitan Asylum Hospitals on Saturday last (of which 21 were admitted during the week), and 7 in the Highgate Small-pox Hospital. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 1226, against 1202 and 1230 on the preceding two Saturdays; 126 new cases were admitted during the week, against 96, 117, and 146 in the previous three weeks. The deaths referred to diseases of the respiratory organs in London, which had risen in the preceding three weeks from 379 to 523, declined again last week to 466, and were 35 below the corrected average. The causes of 86, or 2·0 per cent., of the deaths in the thirty-three towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Croydon, Brighton, Norwich, Sunderland, and in four other smaller towns; the largest proportions of uncertified deaths were registered in West Ham, Nottingham, Salford, and Blackburn.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had increased in the preceding three weeks from 22·5 to 24·2 per 1000, declined to 23·4 during the week ending March 26th, but was 1·1 above the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 19·1 in Dundee and 19·6 in Edinburgh to 24·8 in Greenock and 26·2 in Glasgow. The 650 deaths in these towns included 34 which were referred to whooping-cough, 12 to measles, 9 to diarrhœa, 8 to diphtheria, 5 to "fever," 1 to scarlet fever, and not one to small-pox. In all, 69 deaths resulted from these principal zymotic diseases, against numbers increasing from 62 to 71 in the preceding four weeks. These 69 deaths were equal to an annual rate of 2·5 per 1000, which slightly exceeded the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of whooping-cough, which had been 29 and 28 in the preceding two weeks, rose again last week to 34, of which 21 occurred in Glasgow, 3 in Edinburgh, 3 in Aberdeen, and 3 in Leith. The deaths referred to measles, which had been 16 and 15 in the previous two weeks, further declined to 12 last week, all of which were recorded in Glasgow. The 8 fatal cases of diphtheria exceeded by 3 the number in the preceding week, and included 3 in Glasgow, 2 in Dundee, and 2 in Aberdeen. The deaths referred to different forms of "fever," which had declined from 8 to 4 in the preceding three weeks, were 5 last week, of which 3 occurred in Glasgow and 2 in Dundee. The deaths referred to diseases of the respiratory organs in these towns, which had been 154

Digitized by Google

and 183 in the preceding two weeks, were 181 last week, and exceeded by 15 the number in the corresponding week of last year. The causes of 57, or nearly 9 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had increased in the preceding three weeks from 32·7 to 36·8 per 1000, further rose to 40·1 during the week ending March 26th. During the past twelve weeks of the current quarter the death-rate in the city averaged 38·5 per 1000, the rate for the same period being 28·7 in London and 19·9 in Edinburgh. The 269 deaths in Dublin during the week under notice showed an increase of 22 upon the number in the preceding week, and included 22 which were referred to measles, 5 to whooping-cough, 3 to diarrhœa, 1 to "fever," and not one either to small-pox, scarlet fever, or diphtheria. In all, 31 deaths resulted from these principal zymotic diseases, equal to an annual rate of 4·6 per 1000, the zymotic death-rate during the same period being 2·7 in London and 1·2 in Edinburgh. The fatal cases of measles, which had been 12 in each of the preceding two weeks, rose last week to 22, and exceeded the number recorded in any week since August, 1887. The deaths referred to whooping-cough, which had declined from 8 to 5 in the previous three weeks, were again 5 last week. The 3 fatal cases of diarrhœa exceeded the number in any recent week. The 269 deaths in Dublin last week included 32 of infants under one year of age, and 97 of persons aged upwards of sixty years; the deaths of infants showed a slight decline, while those of elderly persons considerably exceeded those recorded in any recent week. Seven inquest cases and 3 deaths from violence were registered; and 94, or more than a third, of the deaths occurred in public institutions. The causes of 24, or nearly 9 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

THE farewell banquet to Surgeon-Major-General J. Sinclair by the officers of the Medical Staff quartered in Ireland took place at the Shelbourne Hotel, Dublin, on Thursday, March 31st, when a large assembly of guests was present. Surgeon-Major-General Sinclair has earned deserved popularity with the officers of his department during the time he has filled the position of Principal Medical Officer in Ireland, and his retirement, although compulsory on completion of sixty years of age, is much regretted. Surgeon-Colonel W. Collis, now Principal Medical Officer, Cork, will, as previously announced, succeed Surgeon-Major-General Sinclair.

The death is announced of Brigade-Surgeon William Jobson on March 21st at Edinburgh.

ARMY MEDICAL STAFF.—Surgeon-Colonel Alexander Frederick Bradshaw, C.B., to be Surgeon-Major-General, vice W. Thomson, M.B., retired; Brigade-Surgeon-Lieutenant-Colonel Charles Henry Young Godwin to be Surgeon-Colonel, vice A. F. Bradshaw, C.B.; and Surgeon-Lieutenant-Colonel Philip Lefeuvre Kilroy to be Brigade-Surgeon-Lieutenant-Colonel, vice C. H. Y. Godwin (all dated March 10th, 1892); Surgeon-Captain Richard Hugh Penton is seconded for service with the Egyptian Army (dated Feb. 12th, 1892).

NAVAL MEDICAL SERVICE.—The following appointments have been made at the Admiralty:—Staff Surgeon Robert W. Biddulph to the *Sirius* (undated); Surgeon Robert W. Senior to the *Sirius* (dated April 5th, 1892).

HOSPITAL AND DISPENSARY, SCARBOROUGH.—During the past year substantial progress appears to have been made towards providing a new hospital, the erection of which was determined upon at the last annual meeting. A site in Westgate has been obtained, on which the new building is being erected. The honorary treasurer's statement of accounts showed a balance in hand of £91 2*s.* 7*d.* The report concludes with a sympathetic reference to the loss the hospital has sustained by the death of the late Dr. John W. Taylor, who for twenty-one years had rendered the institution continuous valuable services in several important official posts.

THE OPIUM QUESTION.

To the Editors of THE LANCET.

SIRS,—As you have given your adhesion to the anti-opium agitation, and as 5000 medical men have signed a declaration to the same effect, the opportunity seems a favourable one for clearing up some difficulties which surround this controversy. We have had a good deal of declamation, many dogmatic statements, and much sentiment of a highly respectable kind; but the solid foundation of fact on which this fabric should be built lacks stability, if indeed it can be said to exist at all. It is obvious that unless satisfactory proof can be given of the disastrous effects of the opium habit on the human constitution, England must be allowed to leave the court without a stain on her character. I have long been trying to get this information, but until now I have completely failed. But observing among the names of those who have memorialised the Government on the anti-opium side professors of materia medica, of pathology, and of medicine, physicians and surgeons to large hospitals, and others of our professional leaders, I invite them to step out and enlighten our darkness. They can hardly have lent the weight of their authority without full knowledge and consideration and an ample sense of the responsibilities attached to their position.

It is surely not too much, therefore, to ask them to justify the faith that is in them by supplying information on the following points:—1. Does the opium habit directly shorten life? 2. Has any death been certified as due to opium eating or smoking? 3. What are the symptoms observed by competent medical observers? 4. Give some pathological detail of the tissue degenerations noted. 5. Admitting that morphia is not volatilised by heat, but is largely if not entirely destroyed by the heat of the pipe, which constituent of opium causes the alleged ill effects? 6. Is it not the case that the Sikhs and the Rajpoots, the finest and the most warlike races of India, take opium regularly and thrive on it? 7. Is it not equally the fact that large numbers of the educated Chinese also take opium regularly without bad results? Some answer to these queries, couched in good set scientific phraseology, and backed up with statistical detail, will be of great service to the cause of truth. I am, Sirs, yours faithfully,

Reform Club, March 28th, 1892. ROBERT FARQUHARSON.

To the Editors of THE LANCET.

SIRS,—I thank you for the consideration which you have given to the contentions of the side I take on the opium question; but I do not allow your argument to be conclusive. The habit of opium smoking is not more unnatural than the majority of popular indulgences; and every indulgence is justified by a certain amount of therapeutic or tonic effect which it produces. More than 15,000 Chinese coolies, the greater part of whom smoked opium, passed through the hospitals of which I had superintendence, and I decidedly hold that the popular use of alcohol does more harm than the use of opium. I asked you to compare the Hindoo who takes alcohol with the Chinaman who takes opium, and have no doubt that the Chinaman will be found the less deteriorated of the two. So much for the question as to which is the greater evil. The task you now set before us is to make the Chinaman moral and temperate by restricting his alcohol and limiting his opium smoking. It is a hopeless task. India supplies the best opium under elaborate safeguards. Stop its production in India, and you will very much harm the cultivators and cripple the resources of the Government, while you will not benefit the Chinaman. Large amounts of opium are readily procured from South-west China, although, on account of its inferior quality, it does not sell in competition with the Indian article, but abundance of opium can always be got. When it is shown to be possible to efficiently regulate the sale of all luxuries which may be noxious by unrestrained use, it is time for Government to interfere. But even in England a way has not been found to limit the sale of alcohol and opium to purely therapeutic purposes. We

Some answer to these qu couched in good set scientific phraseology, and with statistical detail, will be of great service in the of truth.

I am, Sirs, yours faithfully,
ROBERT FARQUH

Reform Club, March 28th, 1892.

To the Editors of THE LANCET.

SIRS,—I thank you for the consideration with given to the contentions of the side I take on the question; but I do not allow your argument to clusive. The habit of opium smoking is not more than the majority of popular indulgences; and dulgence is justified by a certain amount of tonic effect which it produces. More than half coolies, the greater part of whom smoked opium through the hospitals of which I had superintend I decidedly hold that the popular use of alcohol harm than the use of opium. I asked you to Hindoo who takes alcohol with the Chinaman who opium, and have no doubt that the Chinaman is the less deteriorated of the two. So much for the as to which is the greater evil. The task you before us is to make the Chinaman moral and not by restricting his alcohol and limiting his opium It is a hopeless task. India supplies the best elaborate safeguards. Stop its production in India you will very much harm the cultivators and the resources of the Government, while you do benefit the Chinaman. Large amounts of opium are procured from South-west China, although, as is its inferior quality, it does not sell in competition Indian article, but abundance of opium can be When it is shown to be possible to efficiently sup sale of all luxuries which may be noxious by use, it is time for Government to interfere. Sure a way has not been found to limit the d to purely therapeutic purposes

have not stopped the abuse of alcohol at home any more than we can stop the use of opium in China. But the Indian Government exerts itself to minimise the injurious use of the drug. It is not in the power of the authorities to extirpate a national habit. Indian opium is much more expensive than native Chinese, and in consequence less used by the poorer classes than by the well-to-do. It is an important consideration that probably the composition of Indian and Chinese opium is different, and that the proportion of the alkaloids varies. I believe that the finer quality of Indian opium is less injurious and causes less ultimate mischief than the other coarser varieties. Until it is absolutely guaranteed that alterations in the present system of production will not cause additional harm, by the extension of the use of alcohol or otherwise, it is well to remember the motto, "*Quieta non movere.*" The practical question is not really affected by the fact that a single overdose of opium is much more serious than a single overdose of alcohol. It is a consideration regarding habitual use which is before us. I see no reason to alter my previous conclusions:—1. The habitual use of opium is not so dangerous nor so degrading as the "anti-opium party" represents. 2. The importance of forbidding the export of opium from India with a view to lessening its consumption in China has been exaggerated. 3. To place restrictions under present circumstances on opium consumption is likely to cause harm by stimulating the use of other more dangerous forms of indulgence.

I am, Sirs, yours faithfully,
March 29th, 1892. W. D. S.

P.S.—I may add that I sympathise with all efforts to decrease vice and lessen misery, especially of semi-civilised races. The introduction of the "fire-water" to the races unaccustomed to it is a story of disgrace. On the other hand, I am convinced that the present endeavour to raise a crusade against opium is an example of misguided zeal.

To the Editors of THE LANCET.

SIRS,—At a very crowded meeting at the Society of Arts on Thursday, March 24th, a paper was read by G. Batten, Esq., late of the Bengal Civil Service, with Sir John Strachey, K.C.S.I., formerly Lieut.-Governor of the North-West Provinces and Oudh, in the chair, on "The Opium Question." The reading of this paper was preceded by a remarkable article in *The Times* of March 21st, of two and a half columns, on this subject, the main object of which seemed to be to show that, apart from the question of economic revenue, "the legitimate use of opium in India is determined by two sets of causes—by geographical or climatic necessities, and by needs arising out of the prohibitions of religions, or the temperament of races"; or, in other words, the issues were limited to purely medical and moral lines. The latter we can surely dismiss with the remark that, if there is any force left in the precept to do to others as we would be done by, the obligation devolving on a professedly Christian nation to supply its subjects with an inducement to self-indulgence in lieu of another prohibited by their religious enactments, or to minister to a temperament—alas! already admittedly sensual—by means of a drug, whatever may be said to the contrary, largely taken for sensual purposes, is as baseless as it is immoral.

The medical aspect of the question, however, is one which must be carefully and scientifically discussed; for, if it can be satisfactorily proved that "the general and moderate use of opium" under any conditions imparts to the poor cultivator of India what the writer in *The Times* describes as "an unconscious safeguard" against the endemic diseases of any locality, by far the chief of which is fever (I purposely do not limit the locality to the population of deltaic tracts of land), then the opium question must be discussed apart from all considerations other than those which will enable the peoples of India to resist most successfully that disease (fevers of varied types) which annually carries off numbers out of all proportion to all other diseases put together. For instance, in a population of 44,000,000 in the North-West Provinces and Oudh, the deaths from fevers in 1886 numbered 250,995 This, therefore, is the point round which the battle must now rage, as the withdrawal of the drug said to produce this "unconscious safeguard" is declared by the writer in *The Times* to be "morally indefensible." Opium, therefore, must be viewed, and treated, either as a necessity for health or a luxury for wealth; and perhaps there never was a better opportunity, outside of a purely professional arena, such as that in which I led the discussion at the meeting of the British Medical Association at Bournemouth last year, than was presented at the Society of Arts last Thursday. There were medical men in that splendid hall capable, from the greatest and most varied experience, of discussing the subject to the full, and there were civil administrators in sufficient numbers to witness the combat and test the results; but clearly, quite unexpectedly to all, this crucial point of the question was never even touched upon in the discussion, if we except a few remarks from Sir Lepel Griffin. I must, however, in justice to Sir George Birdwood, state that, owing to the impossibility of giving the numerous applicants to speak an opportunity of being heard, he most generously, on behalf of the Society, undertook to record in the pages of the Society's journal the remarks of those who would have spoken had there been time We must, therefore, wait till the journal appears to read the views of those present. In the meantime, I feel all must admit the difficulty which the chairman undoubtedly experienced in limiting the time of the speakers; but, as I have said, Sir George Birdwood has done his best to supply any deficiency which might have been complained of from this cause.—Yours truly,

ROBERT PRINGLE, M D,
Blackheath, S.E., March 26th, 1892. Brigade Surgeon.

*** Other communications on the above subject are unavoidably held over till next week.—ED. L.

PYRAMIDAL CATARACT.

To the Editors of THE LANCET.

SIRS,—In an abstract of a paper read by Mr. Treacher Collins before the Ophthalmological Society, which appeared in THE LANCET of March 19th, there are a few points upon which I, perhaps, may be permitted to touch, all the more as Mr. Collins has quoted from a paper of mine on the same subject in the last volume of the Ophthalmological Society's reports. It is a great regret to me that I was unable to be present at the reading of Mr. Collins's paper, nor have I the context, but the abstract is a full one. Mr. Collins's work and communication deserve great consideration. He has collected a unique series of cases and presented them with skill. His conclusions are, in the main, similar to those drawn by previous observers in cases of pyramidal cataract following corneal perforation, and, with the exception of his hypothesis in reference to the formation of new capsule, confirm (so far as my memory serves me, for I have mislaid the paper) the observations of Professor Schweigger on a case of pyramidal cataract submitted to him by Dr. Samelson. So far, then, his cases, admirable as they are, give no new insight into this affection; but Mr. Collins touches very debateable ground when he divides his cases arbitrarily into groups and selects the one suited to establish a particular view. This is equally open to other observers, and the chaos that must ensue is obvious. In referring to a paragraph in my paper, "that pyramidal cataracts are found in a majority of cases associated with clear corneæ," Mr. Collins is not logical in challenging the statement on the ground "that a large number of eyes with opaque corneæ have not been examined," because my paper obviously refers to cataracts *in esse*, and not to those *in posse*. I join issue with any observer who demurs to the presence of pyramidal cataracts with clear corneæ, assuming that he accepts, as I do, the usually received examples of anterior polar capsular opacity with prominence more or less marked, for within the last three months I have removed by suction two zonular cataracts with pyramids on the centre of each capsule, both corneæ being cloudless. In each the pyramid, which certainly lay outside the capsule, was carefully detached experimentally before rupturing the capsule, and it sank, a thickened, chalky flake, to the bottom of the anterior chamber—a typical example of dead pupillary membrane.

I am, Sirs, yours truly,
P. H. MULES,
March 28th, 1892. Surg., Mid-Cheshire District Eye Hosp.

TUBERCULIN.

A la Direction du LANCET.

TRES-HONORÉS COLLÈGUES,—Je vous prie d'avoir la complaisance d'insérer dans votre journal ce qui suit:

Dans la *Allgemeine Medicinische Central Zeitung* de 20 février nous lisons: "Un médecin suédois, Dr. O. Torstensson à Gothebourg, a reçu à une demande qu'il

Digitized by Google

avait faite au Professeur Koch, de l'assistent de celui-ci, du Docteur A. Libbertz, la réponse suivante:—'Je suis fâché de n'être pas à même de vous envoyer la soi-disante tuberculine améliorée dont on a parlé dans les journaux. A la vérité, le Professeur Koch s'occupe continuellement à perfectionner son remède, et il croit de ces jours être plus près de son but. Cependant, il est d'avis de ne pas publier la préparation avant qu'elle ait été soumise à une épreuve brillante dans des maladies tuberculeuses. C'est pourquoi il n'est pas permis de s'en servir hors des cliniques du Professeur Koch.'" Le même journal nous mentionne, sous date 12 mars: "Dans les baraques de maladies contagieuses sous la direction du Professeur Koch soixante hommes, trente six femmes, et six enfants peuvent être admis. A présent environ soixante-dix personnes y sont traitées de la tuberculine améliorée." Nous voyons que M. le Professeur Koch s'occupe encore toujours de recherches pour améliorer, purifier, et perfectionner son soi-disant remède. Donc, il a été de sa part un fait sans doute un peu précipité et prématuré d'avoir préconisé, il y a un an et demi, son procédé comme capable de guérir la tuberculose. Il me semble, cependant, plus à propos d'arrêter d'abord l'existence de ces microbes que de chercher à perfectionner un remède jusqu'ici inutile, sans valeur, et même dangereux, basé sur les qualités de prétendus microbes dont je dois nier l'existence. Qu'il nous montre les bacilles tuberculeux dans ces endroits où jusqu'ici il manque de nous les montrer, et où il doit nous les faire voir en premier lieu—c'est à dire, dans des tubercules en développement, dans des tubercules tout à fait développés, encore frais, crûs, et dans des cavernules qui ne sont pas encore en rapport avec les bronchioles, et de plus dans une disposition et une agrégation conformes à la nature et à l'arrangement des parasites dans des affections vraiment parasitaires—s'il veut que nous ajoutions foi à l'existence de ces microbes et à leur rapport étiologique avec la tuberculose. Car, si les bacilles tuberculeux n'existent pas, comme je prétends, il ne peut pas être question d'un extrait ou d'un produit de ces microbes illusoires.

Agréez, Messieurs, l'assurance de mes sentiments distingués et mes salutations sinceres.

Groningue, 23 mars, 1892. H. W. MIDDENDORP.

MEDICO-LEGAL CORONERS.

To the Editors of THE LANCET.

SIRS,—The leading article in THE LANCET of March 19th raises the question "How are suitable medical candidates to be obtained?" To secure this object I would suggest that the appointment as coroner should be competed for, after a course of special training in the various medical and legal subjects required. Competitive examination would be the surest means of securing the best men for such an important post. Coroners' inquests should be presided over and conducted by gentlemen well qualified in law as well as medicine. The course of study should therefore include practical and theoretical training in the requisite subjects appertaining to both professions. A medical coroner without legal knowledge is at a great disadvantage, but a legal coroner without knowledge of medical science is much worse. That coroners' courts should be presided over by gentlemen specially qualified for the purpose would be an extreme source of satisfaction to the medical profession and an additional security to the public. Inquiry into the cause of death is a purely medical investigation, but in the conduct of it legal points arise which a medico-legal coroner would be prepared for. As matters stand at present, verdicts are frequently returned as to the "cause of death" where no medical evidence has been called, and where both coroner and jury make most egregious mistakes. In these cases the jury are, to be sure, entirely dependent on the coroner, and therefore not so much to blame. I have frequently known of verdicts of "Natural causes" &c. being returned where medical evidence was dispensed with, which would have undoubtedly proved that the causes were decidedly "unnatural." Country jurors, as a rule, are not capable of grasping the salient points in medico-legal investigations; it is therefore most important that scientific questions, when they arise, should be explained to them in a concise and lucid form. I think coroners' courts require complete reformation. It seems absurd to expect twelve men, "good and true" as they may be, whose mental development has decidedly suffered from their station in life, to deliberate on scientific matters of which they must be totally ignorant. I do not purpose discussing the mode of reformation, but I think medical facts can only be properly judged of by medical minds.—I am, Sirs, yours truly,

March 23rd, 1892. M.R.C.P.I.

*** Our contention has always been that the amount of knowledge of law governing the coroner's functions may easily be acquired by a medical man, whereas, on the other hand, the medical knowledge requisite to conduct an inquiry into the cause of death can only be possessed by one who has received a competent medical training.—ED. L.

FATAL CASE OF INHALATION OF ROBURITE FUMES.

To the Editors of THE LANCET.

SIRS,—I was present at the inquest noted in THE LANCET of March 19th by Dr. Hatton, and venture to think we cannot accept the *ipse dixit* of a coroner's court upon a scientific question. For many years I have had a large number of cases under my care, of both acute and chronic cases of nitro-benzol poisoning, and the symptoms described by Dr. Hatton do not in the least tally with my experience; neither do the post-mortem appearances. In over two hundred cases I have never observed nystagmus, but we are all aware that it is common, irrespective of poisoning, amongst colliers. Indistinctness of vision only occurs in prolonged and very chronic cases. Temperature I have never found over 100°. Cyanosis is common during life, and by German observers said to exist after death, but in the fatal case which I had, paleness of the mucous membranes and body generally was one of the most marked characteristics. The reflexes are usually much enfeebled, and in acute cases lost. Meningitis and encephalitis are not, so far as I have observed, produced by the absorption or inhalation of this vapour; and Professor Paul, in his cross-examination, said that he was unaware that nitro-benzol could produce inflammation of the brain. I have seen men inhale a concentrated atmosphere of nitro- and di-nitro-benzol vapour fifteen minutes at a time, and only suffer temporary inconvenience in consequence. Therefore it seems to me improbable that a fatal case should occur in a healthy man from breathing an atmosphere so slightly tainted with nitro-benzol as the evidence of the court amply proved. I was also present at most of the underground experiments by Professor Dixon and Messrs. Mounsey and Hannah, with the ventilation absolutely stopped during the explosion of roburite cartridges for from twenty to thirty minutes, and felt no inconvenience. It seems to me advisable for medical men to be very careful before attributing fatal results to the use of any explosive used in mines, especially one which, theoretically, is so innocuous in the fumes which it gives rise to, and one which on all occasions, when practically and scientifically tested, has been shown to be harmless.

I am, Sirs, very faithfully yours,

R PROSSER WHITE, M.D., M.R.C.S.,
Hon. Surgeon, Royal Albert Edward Infirmary, Wigan.

March 29th, 1892.

SUBPERITONEAL HYSTERECTOMY.

To the Editors of THE LANCET.

SIRS,—Dr. Heywood Smith, in his interesting article on subperitoneal hysterectomy in THE LANCET of Feb. 20th, 1892, refers to a paper of mine on the same subject. He mentions the chief points of my method—viz., the raising of peritoneal flaps, the separate ligature of the uterine arteries, and the avoidance of the ureters &c.; but he has not, I think, quite grasped their importance, in that he regards them as subsequent in time to the removal of the tumour.

The steps of my method in their order are—(1) abdominal section; (2) separation of adhesions, if present; (3) ligature and division of both broad ligaments; (4) formation of anterior and posterior peritoneal flaps, each incision starting in the lower angle of the peritoneal wound formed by the division of the broad ligament on the one side and ending at the same point on the other; (5) separation of the peritoneal flaps from the uterus on all sides down to the insertion of the cervix uteri into the vagina; (6) seizure and division of the main trunk of the uterine artery of either side, as it lies in the superficial tissues of the exposed cervix uteri; (7) the removal of the tumour and uterus by section of the cervix above the point of ligature of the uterine arteries; (8) suture of peritoneal flaps; (9) complete closure of abdo-

SUBPERITONEAL HYSTERECTOMY.

To the Editors of THE LANCET.

... his interesting case ... Feb. 3rd ...

minal wound. The advantages claimed for the method are—(1) after division of the broad ligaments, and until the suture of the peritoneal flaps, all operative procedures are outside the peritoneum, and away from all sources of danger; (2) the operation is practically bloodless; (3) the peritoneal cavity is left closed and clean; (4) the stump is left unbruised by the application of any elastic ligature.

I note that in all three of Dr. Heywood Smith's cases an elastic tourniquet was used, that in two cases he had suppuration, and in the third a hæmatocele, all of which, owing to the excellence of his suture, were extra-peritoneal. In all surgical procedures I take it the first aim is to diminish, as far as possible, the introduction into the wound of noxious elements, be they germs, germ products, or germicides; the second is to injure as little as possible the tissues left behind, for in these tissues the healing process, with its extraordinary tendency to degenerate into inflammation, has to take place. The application of a tourniquet in an amputation of an extremity is attended with but little risk, partly from the facility with which it is properly applied, partly from the strong resisting power of the skin and subcutaneous tissue, and partly from the distance between the point of application and the tissues which have to heal. In the application of a tourniquet to the uterus the exactly opposite obtains, and I think the results will be rendered more perfect and the operation more bloodless by the ligature of the main trunks of the uterine arteries before removing the tumour.

I am, Sirs, yours faithfully,

Cairo, Feb. 28th, 1892. HERBERT MILTON.

WINTER COUGH AND NOSE OBSTRUCTION.

To the Editors of THE LANCET.

SIRS,—The frequency of chronic winter cough, laryngeal catarrh, and cold in the head is unfortunately, in this country, Europe, and America, notorious. I have recently shown from the examination of over 1000 living and 5000 dried skulls that some irregularity of the nasal septum, causing more or less obstruction to nasal respiration, is a constant feature of nine out of every ten persons living in those countries. Facts are steadily accumulating, and the conviction is becoming established with many who are competent to judge "that chronic winter cough, laryngeal catarrh, and post-nasal catarrh, with all their consequences, are in the majority of cases the direct result of breathing unfiltered, cold, and dry air that has not passed through the proper respiratory gate." This proposition can only be refuted by evidence to the contrary, and established by showing that every person suffering from winter cough or laryngeal catarrh, or a great majority of these, has some marked obstruction in the nose. This investigation is now proceeding at several centres, and it is with the object of still further directing attention to the subject that I write this letter, and subscribe myself

Your faithful servant,

MAYO COLLIER, M.S. Lond., F.R.C.S. Eng.

New Cavendish-street, W., March 24th, 1892.

MR. BARFORD AND WELLINGTON COLLEGE.

To the Editors of THE LANCET.

SIRS,—Mr. Barford appeals to me in your columns with respect to three cases of sore-throat which occurred some years ago in my own family, and which were attended by him in the course of private practice. Will you allow me to answer his appeal by one question? If he considered them at the time to be cases of diphtheria, as he now thinks that he did, why did he not advise any quarantine or measures of disinfection? There were three young children in the house, and boys of the school were constantly in and out of it.

I am, Sirs, your obedient servant,

Malvern, March 28th, 1892. E. C. WICKHAM.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The Queen's Hospital.

THE fifty-first annual meeting of this institution was held on the 28th ult., the president, Lord Leigh, in the chair. It was stated that the report was both gratifying and encouraging. There had been a large increase of patients, the sanitary condition of the hospital was eminently satisfactory, while the nursing scheme had proved to be very valuable and useful. The report further stated that the average residence of in-patients was 21·1 days, while the death-rate was exceptionally low, and the management very complete and well organised. The usual votes of thanks were passed, and the Earl of Dudley was elected president for the ensuing year.

The Ingleby Lectures.

Dr. Foxwell, the Ingleby lecturer for the year, gave the first of a series of lectures at Queen's College on the 29th ult. The subject taken was "The Condition and Treatment of the Vascular System in Chlorosis and other Debilitated States." After sketching the life of the founder and the origin of the lectures, Dr. Foxwell delivered an interesting lecture to an appreciative audience. The practice of living at a pressure beyond the strength of the individual capacity was dwelt upon and the evils pointed out. The errors of pressure in child life, before development is complete, received attention, and condemnation was expressed at the common practice of returning to work too quickly after a severe illness. Two more lectures will complete the series.

The Medical Institute.

The annual report has just been issued and is considered to be satisfactory. The register established last year for the registration of locum tenens, dispensers, and nurses has not been a success owing to the small number of names sent in. The financial statement shows a deficit of £29 8*s.*; £12 more than last year has been expended in books, and in the course of the year 1216 volumes were issued to 125 borrowers.

Assize Cases.

Two cases of some importance to the public were tried at the local assizes recently, both of which have had considerable local interest. At the Staffordshire assizes John Goodall was sentenced to two years' imprisonment with hard labour for indecently assaulting Mrs. Siddalls in a railway carriage near Tamworth. The points emphasised were the want of separate compartments for ladies travelling alone, of adequate means of communication with the guard in cases of necessity, and of communication with the adjoining compartment. Two medical students who were travelling in the next compartment when the victim fell from the foot-board were the principal witnesses for the prosecution. The second case is still a mystery. A boy was sent with his father's breakfast, never returned, and his body was found, stripped of clothes, in the canal. The two prisoners escaped the more serious charge, but pleaded guilty to stealing the boy's clothes, which they say they fished out of the canal. How the boy came to be without his clothes and how he got into the canal are questions which remain undecided.

March 30th.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

Strikes and their Effects.

THE effects of the present unfortunate strike of engineers, which has now gone on about seven weeks, are now being very severely felt in Newcastle and district. In Newcastle and Gateshead alone the *Newcastle Chronicle* computes that not fewer than 2000 people are actively engaged in the alleviation of poverty, and the amount contributed for its relief has now reached £200 a day. This does not take into account private benefactions and an immense amount of aid in many ways which is not published. At South Hetton, and many other colliery villages, the people are suffering from a scarcity of water which, it is feared, may lead to much illness before long. This scarcity may be termed entirely artificial—that is, there is abundant water, but the strike leaders refuse to allow any of the hands to work the pumps at the collieries whence the water is supplied; hence, as regards water, their families may be said to be starving in the midst of plenty from this self-imposed "famine." Another matter affecting the sanitary condition of many of the Durham colliery villages is the neglected state of the ashpits and privies. It appears that all cleansing operations are in abeyance owing to the withdrawal of the horses and carters, so that the usual receptacles for dirt and rubbish

Digitized by Google

are filled and overflowing. This is bad enough in itself, but when taken in conjunction with a scarcity of water is certain ere long to lead to disease. The Weardale Lead Mines have been closed owing to the Durham strike, and the cessation of work is reported to have already caused intense suffering, as many of the inhabitants are already without coals, and are solely dependent on their neighbours for what peats can be obtained. The lead miners of Weardale are a very hard-working class, and at the best of times earn very low wages. The weather, too, in the mountain districts of Durham has become very severe.

Ambulance Work in the North.

The annual meeting and concert of the Elswick Collieries Ambulance Association has been held in Newcastle. Among the miners and others employed at the collieries the greatest interest has been taken in ambulance work, and the men and their families were present in large numbers, requiring one of the largest chapels in Newcastle to accommodate them. The chairman, in the course of his remarks, said that the death-rate in mining was smaller than in many other industries, but in collieries there were a great many minor accidents which it was impossible to avoid. Ambulance students could do a great deal of good by attending to such cases, and at Elswick their success had been very marked. Mr. May, the colliery surgeon, had also been their kind and successful ambulance instructor. Dr. Jack of Rothbury will recommence his course of ambulance instruction shortly. Dr. Robson last week gave a *résumé* of his course, dwelling principally on the circulation of the blood &c. He was at the same time the recipient of a testimonial and presentation from his class.

Anti-Cremation in Darlington.

A meeting in opposition to cremation has been held in Darlington in the Central Hall, and it is reported as being well attended. The usual arguments against cremation were advanced.

Sanitary Lectures.

The first of the course of sanitary lectures under the auspices of the Sanitary Institute and the Newcastle Corporation was given last Saturday in the Guildhall, on Ventilation, Heating, and Lighting, by Dr. Louis C. Parkes. The Sheriff of Newcastle occupied the chair, and there was a numerous attendance, including various members of the Corporation. The course will extend to June next.

Dr. B. W. Richardson in Newcastle.

Dr. B. W. Richardson of London has been lecturing in Newcastle, and on Monday last he gave a special address to medical men of the town and district. Mr. and Mrs. T. H. Bainbridge of Holwood Jesmond provided a breakfast for all medical comers in the Lovaine Hall, and the proceedings were very interesting. Whatever may be thought of Dr. Richardson's views on the alcoholic question, and he did not put them at all in an unreasonable way (from a medical point of view), we all respect him for his work as a physiologist and as a sincere social reformer. The hearty welcome that he received in Newcastle could leave no doubt that we were all glad to see him.

Mr. Thomas Ironsides of Kibblesworth Farm, near Gateshead, who will be 101 years of age on April 12th, recorded his vote for the recent County Council election, and is in good health.

Newcastle-on-Tyne, March 30th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

Aberdeen University.

THE medical "professional" examinations will terminate on Thursday, and the graduation ceremony will take place on Monday. Admission to the graduation hall is on this occasion to be by ticket. There are seventy-eight candidates for the final examination. The University Extension Fund continues to make very satisfactory progress, and the success of the scheme is now ensured by the announcement that the Government will this year vote a grant of £5000 as a first instalment of £40,000. Where and how the buildings are to be extended is still a vexed question. In Monday's *Free Press* Professor Trail begins a long article on the subject by saying: "Three weeks since, through your columns, I ventured to state that no extension of the buildings of the University of Aberdeen at either of the present sites would prove permanently satisfactory; that to render the University what it ought to be in future, and, indeed, must be if its reputation is to be retained, it should be removed to a new site; and that the best possible site would be secured could an exchange be effected of Marischal College for Gordon's College."

Health of Aberdeen.

During the past week the following cases of zymotic diseases were notified to the medical officer of health:—Scarlet fever, 9; diphtheria, 2; typhoid fever, 2; typhus fever, 5; whooping-cough, 55; erysipelas, 1. One death from influenza was recorded during the week.

District Nursing for the Poor.

A public meeting was held on Friday, March 26th, in the Aberdeen Music Hall Buildings, to promote the formation of a District Nursing Association for the poor at their own homes. Lord Provost Stewart was in the chair. It was unanimously "agreed to form an association, to be called the 'Aberdeen District Nursing Association,' and to make application to the Scottish Council for the services of a Queen's nurse and for affiliation" with the Edinburgh Association.

March 30th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Measles in Dublin.

THIS disease has become almost epidemic in Dublin, and the deaths have been very numerous for the past few weeks. Every effort is made to induce the parents of children who contract this disease to allow them to be brought into hospital; for it is a remarkable fact that not one of the cases of measles treated in hospital in the year 1891 died. Of course this recommendation only applies to the poorer classes. Sir C. A. Cameron, medical officer of health, has prepared a sanitary circular for distribution among the dwellers in tenement houses, which points out what should be done when measles appears, and shows the necessity of having the patients brought to hospital.

Health of Ireland for December Quarter of 1891.

During the December quarter the births numbered 24,681, and the deaths 21,460. The birth-rate was 0·4 under the average rate for the corresponding quarter, and the death-rate 1·9 above the average. The returns of pauperism show a decrease of 564, or 1·3 per cent., in the average number of workhouse inmates on Saturdays during the quarter as compared with the previous year, and a decrease of 1574 in the average number of persons on out-door relief. The increase in the death-rate was due to the widespread prevalence of influenza and inflammatory diseases of the respiratory system. The aged and debilitated were the chief sufferers, as is demonstrated by the extent of the mortality among persons aged sixty years and upwards, the number of deaths (9300) from all causes at that age period during the quarter being 14 per cent. in excess of the average (8152) for the December quarter of the five years 1886-90. Enteric fever was prevalent in Dublin and to a less extent in Belfast, and whooping-cough caused a rather large number of deaths in those cities and in a few other districts, but the rate represented by the aggregate number of deaths from the principal zymotic diseases was below the average for the December quarter, the mortality from some of the diseases in that group having been remarkably low.

The Proposed Abolition of Visiting Physicians of Irish Lunatic Asylums.

The Council of the Irish Medical Association has addressed a letter to the Lord-Lieutenant, submitting that it is very undesirable that an Order of Council should be carried out, which is to the effect that "When any vacancy shall happen in the office of consulting and visiting physician or apothecary in any district asylum, no person shall henceforth be appointed to fill the same." This order, it seems, was founded on the recommendation of the Lunacy Administration Commission, 1891, in favour of the abolition of the visiting physiciancy as relieving the resident medical superintendents of asylums of responsibility, while not affording the assistance which consultants offer to general practitioners, who take the advice of a surgeon, physician, or obstetrician, according to the nature of the case.

of the buildings of the University of Aberdeen and the present sites would prove permanently unsatisfactory that to render the University what it ought to be in this and, indeed, must be if its reputation is to be maintained should be removed to a new site; and that the King's College site would be secured could an exchange be effected with Marischal College for Gordon's College."

Health of Aberdeen.

During the past week the following cases of infectious diseases were notified to the medical officer of health: Scarlet fever, 9; diphtheria, 2; typhoid fever, 1; relapsing fever, 5; whooping-cough, 35; erysipelas, 1. There was also from influenza was recorded during the week.

District Nursing for the Poor.

A public meeting was held on Friday, March 4th, in the Aberdeen Music Hall Buildings, to promote the formation of a District Nursing Association for the poor in their own homes. Lord Provost Stewart was in the chair. It was unanimously "agreed to form an association, to be known as 'Aberdeen District Nursing Association,' and to make application to the Scottish Council for the services of a trained nurse and for affiliation" with the Edinburgh Institution.

Measles in Dublin.

THIS disease has become almost epidemic in Dublin. The deaths have been very numerous for the past few weeks. Every effort is made to induce the parents of children to contract this disease to allow them to be sent to the hospital; for it is a remarkable fact that not one of the cases of measles treated in hospital in the year 1891 died. Of course this recommendation only applies to the poorer classes. Sir C. A. Cameron, medical officer of health, has prepared a sanitary circular for distribution among the dwellers in tenement houses, which points out what should be done when measles appears, and shows the necessity of having the patients brought to hospital.

Health of Ireland for December Quarter 1891.

During the December quarter the births registered were 24,081, and the deaths 21,460. The birth-rate was below the average rate for the corresponding quarter of the last ten years. The death-rate 1·9 above the average. The returns of marriages show a decrease of 564, or 1·3 per cent., in the number of workhouse inmates on Saturday last as compared with the previous week, and a decrease for the quarter as compared with the previous year, and also as compared with the average number of persons on the registers

the uterus, of a series of hard movable nodules, resembling cancerous masses. A re-examination under the microscope of the tumour removed showed that it was a pure fibromyoma. The patient remained in much the same condition for two months, when one day she passed per rectum a gauze compress enveloped in a hard fæcal mass. All the unpleasant symptoms very soon subsided, and the woman has remained well since that event. This curious occurrence demonstrates the importance of counting sponges and compresses used in such operations, and furnishes one more proof of the harmlessness of foreign bodies which have been rendered thoroughly aseptic. The course of events must have been as follows:—The compress, after having lain encysted, must have excited an attack of peritonitis, with perforation of the intestine. That the occurrence of such a *contretemps* is not altogether unknown in the practice of the most careful surgeons is well attested. One operator now uses in abdominal sections fifteen compresses, hemmed in red, the enumeration of which is carefully made on the completion of the operation. A well-known surgeon once left a forci-pressure forceps in the abdominal cavity. The instrument remained in the cavity for eight months, and was then eliminated through an abscess which formed in the umbilical region. Another relates how he once left a sponge in the abdomen, the patient dying of peritonitis three days after the operation. He no longer employs sponges.

(FROM OUR OWN CORRESPONDENT.)

The Reform of German Anatomical Nomenclature.

PROFESSOR WILHELM KRAUSE, who has resigned his professorship at Göttingen, is coming to Berlin to create a uniform anatomical nomenclature. He has undertaken this task at the instance of the Anatomical Society, which has busied itself for five years past with the question, How the confusion in anatomical nomenclature is to be remedied? This question was thoroughly discussed at the third assembly of that Society in 1889. Professor His of Leipsic showed on that occasion how the present multiform anatomical nomenclature had arisen, and how it could be simplified. It was determined that, in the creation of a new nomenclature, regard must be paid not only to descriptive, but also to general and comparative anatomy and to embryology, and that the reform must be based on a complete list of the technical expressions of anatomy, in which all the changes of meaning which each expression has undergone are stated. It was further decided that all that is good in the present nomenclature should be retained, and that expressions containing proper names should not be dropped. Professor His uttered a warning against going too far in the Germanisation of words derived from the Greek and Latin, on the ground that such a change would render mutual understanding between German and foreign anatomists more difficult. A committee was appointed to arrange for and superintend the work, and it was resolved that the work itself should be entrusted to an anatomist of reputation. The members of the committee elected in 1889 are Kölliker, Oskar Hartwig, His, Kollmann, Merkel, Schwalbe, Toldt, Waldeyer, and Karl Bardeleben; and their number was augmented in the following year by the election of Cunningham of Dublin, Lebouc of Ghent, and Romiti of Pisa, in order that due regard may be paid to the necessities of foreign anatomists. The work was entrusted to Professor Wilhelm Krause, who will have to devote several years to it. The expenses will be defrayed by the Anatomical Society and the Universities of Berlin, Vienna, Munich, and Leipsic.

Statistics.

In the week which ended on March 12th 2 persons died in Berlin from typhus fever, 3 from syphilis, 3 from influenza, 4 from puerperal fever, 5 from erysipelas, 5 from scarlatina, 6 from measles, 9 from diarrhœa with vomiting, 11 from whooping-cough, 12 from gastro-intestinal catarrh, 15 from diarrhœa, 24 from senile decrepitude, 29 from cerebral apoplexy, 53 from pneumonia, and 101 from pulmonary phthisis. There were 18 violent deaths, including 10 cases of suicide. Three persons poisoned themselves, and 1 died from delirium tremens. In the same week the death-rate of Dresden was 20·2, of Berlin 20·5, of Hamburg 20·7, of Frankfort-on-the Main 22·4, of Breslau 24·5, and of Munich 29·7. Of the German cities with more than 100,000 inhabitants, Elberfeld had the lowest death-rate (17·4), and Aix-la Chapelle the highest (34·9).

The eminent clinical teacher, Professor Rosbach of Jena, has resigned his professorship.

Professor Albert von Kölliker of Würzburg, the Nestor of German anatomists, celebrated the fiftieth anniversary of his graduation as doctor of medicine last Saturday. His age is seventy-five, but his health and strength are excellent.

Protective Legislation for Miners.

DURING the past few years there has been a great loss of life among miners, due to various forms of accident, such as explosions, caving-in of mines, &c. The Pennsylvania Legislature has taken action, and passed a very elaborate and detailed law for the proper management and working of coal mines. The coal-fields are divided into inspection districts, and one inspector is appointed for each by a board of miners and mining engineers. Mine owners are to provide at the collieries an ambulance with stretchers for the purpose of conveying to his home or to a hospital any injured person. No boy under fourteen is allowed to work in a coal mine, and no woman or girl of any age. Boys under twelve cannot be employed in the outside workings. Ventilating currents must be forced along the face of the workings in sufficient volume to sweep away smoke and noxious gases. Inlet and outlet passages are to be separate. Doors must open automatically, and main doors must have an attendant. In mines generating explosive gases all working places must be examined every morning to see if they are safe. Perhaps the most important provision is that requiring two openings from each vein or seam of coal for safe and distinct means of ingress and egress.

Mortality from Influenza.

The New York State Board of Health reports that, of a total mortality of 123,878 during the year 1891, it is estimated that 10,000 deaths are attributable to influenza. These deaths were distributed over the entire State.

A Homicidal Epidemic.

Two or three months since a man called at the office of a wealthy citizen, carrying a grip-sack. He was urgent to see the gentleman, who finally came out to the waiting-room to see his visitor. The stranger gave him a paper to read, which contained a demand for an immense sum of money, under a threat to blow up the building instantly with ten pounds of dynamite, which he alleged to have in his sack. The gentleman attempted to pacify him, meantime withdrawing to his inner office. The visitor followed, threatening, and, as his victim passed through a door, threw the satchel against the wall. A terrific explosion followed. The unknown man was himself blown against a wall, and nothing was left of him but his head, by which he was afterwards identified as an erratic person from Boston. One clerk was blown out of a window into the street, and instantly killed. The gentleman who was assaulted was but slightly affected, though several others in the building were injured. Within a week another gentleman was confronted with a similar demand by a crank who entered his office, and, on refusing, was shot, but not fatally. Soon after one of the most popular clergymen of the city was fired at three times one Sunday as he was entering his house after the morning service, his assailant being a tramp whom he had often befriended. This event was followed by an attempt of an armed crank to gain entrance to the residence of one of the wealthiest men of the city, whose brains, he alleged, he wished to secure that he might also obtain wealth. Another tramp made an attempt on the life of a citizen whose money he demanded, but was arrested before he could do harm. Finally, a popular Jewish rabbi was quite recently shot in the abdomen in his own house by a poor wretch whom he had often aided, because he refused to give him a large sum of money. Fortunately the ball glanced, and did not penetrate the cavity of the peritoneum. These wandering homicides have all proved to be persons who have either previously been in insane asylums or who have been regarded as of unsound mind.

Leprosy in Honolulu.

The Bureau of Medicine and Surgery of the

Navy has issued a report on the treatment of leprosy in Honolulu, Sandwich Islands, of some importance. The report is based on the investigations of Dr. Lutz of Brazil, an associate of Unna of Hamburg, who was an experienced dermatologist. Salol was his chief remedy. According to his observations leprosy was associated with inflammatory conditions and with febrile excitement always, and salol, acting as an antiphlogistic and febrifuge, stayed the morbid processes. Creasote and guaiacol, its active principles, were given in cases where the lungs were affected, with satisfactory results. Antipyrin gave great satisfaction in cases where there was neuralgia. Arsenious acid did not act favourably, contrary to common experience, and antisyphilitic remedies were not clearly beneficial in uncomplicated cases. In external use chrysarobin, or chrysophanic acid, was used, and acted favourably in causing the absorption of tubercles and the disappearance of maculo-nervous and psoriasis-like eruptions. It also improved extensive areas of paræsthesia. Chrysarobin was employed in from 5 to 10 per cent. ointments, or in solution with benzene or chloroform, or similar solvents, covered with elastic collodium. Pyrogallic acid was found to act like chrysarobin, but more slowly, and was only employed on the face and hands to avoid toxic symptoms. Ichthyol is praised as combating inflammatory symptoms, and was used both externally and internally. Creasalol is mentioned as a substitute for salol.

Hospital Sunday Fund at New York.

The collections for hospitals on the Sunday set apart for that purpose have gradually increased, until they now reach the respectable figure of $1000. The basis of distribution is the number of free hospital days in each institution. Thirty-one hospitals received from the Fund, representing 545,855 free hospital days.

Bichloride of Gold Cure for Inebriety.

This method of curing inebriety is gaining in popular favour, notwithstanding the many proofs that it is useless and possibly dangerous. New institutes are being created, to which the wealthy inebriates flock in great numbers. After being subjected to a course of hypodermic injections of the gold, being kept meantime from all intoxicants and liberally fed, they are pronounced permanently cured. Some have been so thoroughly convinced of their immunity that they have maintained a stout resistance to temptation for a considerable period. But such large numbers have entirely failed and have returned to their former habits that it has been demonstrated that there is no virtue in the remedy. Some distrust as to its safety has been created by several sudden deaths in these institutes where the patients are under treatment.

Professor Roberts Bartholow.

Professor Bartholow has recently been committed to an insane asylum. The evidences of mental aberration have been of slow development, and for a considerable period he continued to lecture and write with great vigour. At length the faculty of the medical college was obliged to request his resignation in the midst of his course of lectures. He declined, and was compelled forcibly to leave the college. He subsequently published very interesting papers, which showed no mental decline or aberration. His malady, however, progressed, and his condition became such that his friends had no alternative but to place him in an asylum. Professor Bartholow was an active surgeon in the Civil War, and on his retirement located in Cincinnati in connexion with a medical college. He gained a wide reputation as a writer, especially on therapeutics. He was soon called to the Jefferson Medical College, Philadelphia, where he long occupied the first position in the profession. He was a tireless worker, and is believed to have brought on his trouble by overwork.

New Buildings for the Jefferson Medical College of Philadelphia.

The Board of Trustees and the Faculty of the Jefferson Medical College have just completed the purchase of two large lots on Broad-street, giving them a frontage of about 300 ft. and a depth of 150 ft., upon which they will proceed to erect at once a handsome hospital, lecture hall, and laboratory building. The estimated cost of the buildings is 500,000 dols. The hospital will be built not only as a suitable building in which to care for the sick and injured, but will also be provided with a large amphitheatre for clinical lectures. The basement of the hospital will be given over to the various dispensaries, each of which will be provided with large waiting and physicians' rooms, as well as rooms for direct teaching of students. The buildings will be absolutely fireproof, and provided with patent sprinklers in case their contents catch fire. By the erection of three commodious buildings, the laboratory, where delicate work with the microscope or apparatus is carried on, will be separated from the college hall, where didactic lectures are given, and so will be free from any jarring produced by the movements of large classes. With the hospital on one side affording clinical facilities, and the laboratory on the other side of the college hall for scientific research and training, the college will be most favourably situated for giving thorough instruction in medicine. Further than this, immediately across the street is the Howard Hospital, and on the adjoining corner the Ridgway branch of the Philadelphia Free Library, which contains all the scientific works belonging to this wealthy corporation. The new site is even more favourably situated in regard to the centre of the city than the old one at Tenth and Sansom streets.

March 18th.

[*Corrigendum.*—In the last paragraph of the letter of our New York correspondent, which appeared on the 19th ult., the name "Willand" should have been printed *Willard.*]

Obituary.

SIR WILLIAM BOWMAN, BART., F.R.S.

The unexpected death of Sir William Bowman, Bart., has removed from the scene a distinguished histologist and physiologist, and a most able surgeon. In the earlier years of his life he was one of the most laborious and careful scientific workers in the profession, and, rising on his merits, became at a later period one of the most successful practitioners in London, commanding for some considerable time an income that was equal to, if it did not surpass, that of any of his compeers. Of slender build and pallid complexion, with delicately cut features, he has shown himself, even at the ripe age to which he attained, to be equal to the strain of a busy life in the metropolis, and can scarcely be said to have quite relinquished practice, though his visits to London were restricted to one or two days a week. He died on Tuesday morning, March 29th, at his residence, Joldwynds, near Dorking. He had been ill only about a week, having caught a chill whilst removing his books and manuscripts from his professional residence in Clifford-street. Congestion of the bases of both lungs was followed by pneumonic patches, and led to gradual exhaustion, from which he died. He was born at Nantwich on July 20th, 1816, and was therefore in his seventy-sixth year. His father, Mr. John Eddowes Bowman, was a distinguished naturalist, and a brother of the same name as the father was for some years a demonstrator in chemistry at King's College, and wrote two most useful works on practical analysis. Sir Wm. Bowman, after his early education at Hazlewood School, Birmingham, became a pupil at the Birmingham General Hospital. He entered the medical department of King's College in October, 1837, and obtained the membership of the Royal College of Surgeons in 1839. He was appointed demonstrator of anatomy in 1839, being junior to Sir John Simon, who is now the only King's College medical teacher of that period now living. He was also the curator of the museum, and it was at this time that he became so pre-eminent as a microscopical observer.

The first important addition he made to scientific knowledge was a paper he communicated to the Royal Society, which appeared in the Philosophical Transactions for 1840, on the Structure of Voluntary Muscle, and this was followed two years later by a second and equally valuable article on the Structure and Use of the Malpighian Bodies of the Kidney, in which he showed clearly the precise relations between these bodies and the uriniferous tubules, a description entirely opposed to Müller's, which was then taught, and he gave a most lucid and exact account of the circulation through that organ. Both papers attracted great attention, partly on account of the novelty and interest of the facts which he detailed and also for the direct bearing that they had on pathology. The best evidence of the excellence of the work they contained

Digitized by Google

is afforded by the fact that after the lapse of fifty years and the application of many various methods of cutting, injecting, staining, and mounting specimens, very few points of importance have been added to his account either of muscle or of the kidney, and none of his observations have been disproved, though added to by subsequent observers. Both accounts of these organs have become classical, and will constitute the foundation of all future advances. In 1841 he was elected a Fellow of the Royal Society, and in 1842 he was awarded one of the Royal medals. In 1848 he was appointed a professor of physiology at King's College, having in the previous year published the first volume, in conjunction with Dr. Todd, of a work on the Physiological Anatomy and Physiology of Man. The first volume, containing "The Histology of the Tissues: the Muscular and Nervous Systems, with Senses of Touch and Taste," was completed in two years; but the second volume, containing "The Eye and Ear, Digestion, Absorption, Circulation, Respiration, Animal Heat, Voice, and Generation," lingered for eleven years, and would probably never have been finished had the editors not been assisted for the final chapters by Drs. Lionel Beale and Hyde Salter. The work was a great success. It was throughout well and carefully written, and contained a very large quantity of original matter chiefly from the pen of Bowman. It was, moreover, admirably illustrated. He resigned his professorship in 1855. In Todd's Cyclopædia of Anatomy and Physiology, which was produced at intervals between 1836 and 1859, he contributed the articles on Mucous Membrane, Pacinian Bodies, and Muscle, and these are marked by the like thoroughness which characterised his earlier work. At this period of his life (1840) he was elected with Sir John Simon assistant surgeon to King's College Hospital, but he did not obtain the full surgeoncy until 1856. Here he was noted for his diagnostic skill and for the excellence of his operations. He was, it is said, very indisposed to quit the field of general surgery for the more limited subject of ophthalmology, and he would, it is probable, have continued to combine the two had it not been for the remarkable operative ability displayed by his colleague, Sir William Fergusson, and for the great success that attended his own ophthalmic work, which, after the death of Dalrymple, led to almost the whole of the consulting practice of London falling into his hands. And, indeed, he deserved his position, for, carrying into the domain of ophthalmology the skill that he had previously exhibited in physiology and histology, he applied himself to the study of the eye, and gave the fruits of his inquiries to the profession in his "Lectures on the Parts concerned in the Operations of the Eye and on the Structure of the Retina and Vitreous Humour," which was published in 1849. The book, though small in bulk, contained the results of much careful research, and is still read by every man who pretends to know anything of the literature of this department of the profession. In this, as well as in his other works, his literary style was as good as the intrinsic merit was pronounced; whilst concise, it was always clear. It is not to be regretted that he shunned the labour of writing a complete treatise on diseases of the eye, since his minor papers deal with several of the most difficult and obscure parts of ophthalmic surgery. For example, we find a clear and precise account of the ciliary muscle (tensor choroideæ, Brücke); the structure attachments and functions Bowman accurately described for the first time. These lectures are models of brevity and clearness of detail. In 1851 he read a paper before the Medico-Chirurgical Society, in which he suggested a new method of treatment for cases of epiphora, which was a great improvement on the older plans. It has since become classical, and Bowman's method of slitting up the canaliculus has been performed by every ophthalmic surgeon in these troublesome and obstinate cases. Though not invariably successful, it is certain that in a large proportion of cases the results are good; and even if the simple longitudinal division of the canaliculus is not followed by the free passage of tears into the nose, it yet enables subsequent proceedings to be undertaken with good chance of success. Writing in 1857, six years subsequently, he says, in a paper on Lacrymal Obstructions published in the Ophthalmic Hospital Reports, he had found it possible to treat the greater number of cases mechanically, through the upper or lower canaliculus thus opened at the punctum, by passing probes of suitable size downwards into the nose, thus commanding the entire length of the passages, and not being limited, as by the old method, to occlusion of the nasal duct. He thus avoided the inconveniences of the opening in the skin, then universally practised, and established at the very commencement of the treatment a permanent opening, unseen, and attended by no inconvenience, through which the use of the treatment by probes could at any time be at once resumed in the event of relapse. The method, though widely adopted, has the disadvantage of disturbing or destroying the physiological conditions for the descent of tears into the nose, and the field is still open to the careful student of disease. In 1865 he suggested a modification of the ordinary method of extraction of a cataractous lens adopted at that date, in which iridectomy was performed and the lens lifted out with a spoon or traction instrument; and he also discussed the removal of capsular obstructions, in the course of which he recommended a very serviceable innovation in the treatment, consisting of the introduction of two needles. He also paid great attention to the treatment of detached retina, proposing to relieve or cure the disease by the introduction of needles through the sclerotic—a method which, in his hands, proved in some instances very successful. In yet another paper he discussed the symptoms and treatment of malformed, misplaced, and dislocated lenses, his attention being directed to the point in consequence of the intermittent symptoms of glaucoma that occurred in some of the cases. He contributed to the second volume of the Ophthalmic Hospital Reports another paper on Conical Cornea, a subject of exceptional interest on account of the obscurity attending its etiology and appropriate treatment. He records several cases which were benefited by the operation, that had then been just introduced by the late Mr. Critchett, of Adelaide. Subsequently Sir W. Bowman adopted the plan of trephining the apex of the cone. In the paper above referred to is the first observation on the shadow appearing in cases of conical cornea, which has recently developed into the method named "retinoscopy," employed to determine the refraction of the eye.

One of the latest if not the very last literary work he executed was a singularly appreciative and affectionate sketch of the life of Donders, with whom he had long been on terms of intimacy, written as an obituary notice for the Fellows of the Royal Society, and some of our readers will have received with this notice the fine mezzotint which rendered so well the features of the great ophthalmologist of Utrecht. He was elected an honorary Fellow of King's College in 1855, and has served with unvarying regularity on its Council since 1877. He took a lively interest in the institution of the Ophthalmological Society of the United Kingdom, showing his recognition of its importance and value by becoming the first President, and supporting it by liberal contributions every year. Quite recently a testimonial of a portrait of himself by Ouless was presented to him by a large circle of admiring friends, from which a beautiful engraving was taken, and given by himself to those who subscribed for the original painting. At the same time it was determined to issue an edition of his collected works, which we believe is just ready to be issued, having been placed in the hands of Professor Burdon Sanderson.

Few men have equalled, fewer still have exceeded, Bowman's manipulative dexterity. With thin, delicate, artistic fingers, absolutely destitute of nervous tremor, and with perfect knowledge of the anatomy of the parts with which he was dealing, he obtained good results where good results were possible; and when failure occurred, as unfortunately happens even with the most dexterous, it was rare indeed that he could reflect on his own method of procedure. Yet he could fully appreciate the difficulties of an operation and enjoy the pleasure of overcoming them, and would speak with undisguised satisfaction of his success in any case of an exceptional nature.

Sir William Bowman was one of those who immediately recognised the value of the ophthalmoscope, and was amongst the very earliest to make himself familiar with the use of this most valuable instrument. His mind was always on the alert to avail himself of advances in any part of his subject. No one more quickly understood and followed out in practice the important conclusions of Donders in regard to errors of refraction and the application of glasses for their rectification. No one adopted earlier the suggestions of v. Graefe for the performance of iridectomy in glaucoma, or was more willing to discard it for eserine in appropriate cases when that remedy was discovered. No one took more interest in the question of colour-blindness when that curious subject attracted far less attention than at the present time. His wide knowledge of general surgery and large experience in ophthalmic diseases made his opinion

Digitized by Google

on a difficult case of the highest value, and it was accordingly sought, not only by his own countrymen, but by many foreigners, by whom it was held in not less esteem.

Medical News.

UNIVERSITY OF OXFORD.—The Regius Professor of Medicine has given notice that the final examination for the degree of Bachelor of Medicine will commence on Monday, June 6th, at 10 A.M., in the examination schools. The examination for the degree of Master in Surgery will take place on Thursday, June 16th, and the first examination for the degree of Bachelor of Medicine on Thursday, June 23rd, at 10 A.M.

FACTORY LABOUR.—The French Senate has decided that the time of daily labour for women and children in factories shall not exceed eleven hours.

MISSION TO DEEP-SEA FISHERMEN.—The Princess Louise has consented to be present at the annual meeting of the mission in Exeter Hall on the evening of May 16th. Her Royal Highness will distribute the certificates of the St. John Ambulance Association for first aid to the injured to several of the skippers and mates of the society's medical mission smacks.

THE METROPOLITAN WATER-SUPPLY COMMISSION. A meeting of the Royal Commission on Metropolitan Water-supply was held on Wednesday at the offices of the Board of Trade. There were present Lord Balfour of Burleigh (chairman), Sir G. B. Bruce, Professor James Dewar, Mr. G. H. Hill, Mr. J. Mansergh, Dr. W. Ogle, and the secretary, Mr. F. Gaskell. The question of procedure was further considered, and the means to be adopted for obtaining the information necessary for the purposes of the inquiry. The Commission will meet again next Wednesday.

HOSPITAL FOR EPILEPSY AND PARALYSIS.—Mr. E. Boulnois, M.P., in presiding at the annual meeting of this charity in Regent's Park, held on March 24th, said that from statistics for 1890 which the secretary had placed in his hands he found that the London hospitals supplied 8094 beds, of which 6143 were in daily occupation, and 7800 in- and 1,158,000 out-patients had been treated, at a cost of £606,000. Yet the receipts of the hospitals had only reached £522,000. Mr. Pearce Gould, one of the surgeons, said that a new building, sooner or later, was an absolute necessity, and that the committee should lose no time in raising the £20,000 required as a building and furnishing fund, whether the occupancy of the present premises was to end in nine or ten years or not.

NORTH LONDON CONSUMPTION HOSPITAL.—This institution continues to make steady progress. The annual report for 1891 states that the income for the year was quite up to the average. The in-patients during the year had been 381; the out-patients numbered 2310, of whom 745 were treated at Hampstead and the remainder at the out-patients' department. The committee had succeeded in securing premises in Fitzroy-square for an out-patients' department and offices, the need of which had long been felt. The extension of the building at Hampstead was now being carried out. Sufficient funds were forthcoming to warrant the committee in commencing the erection of the central block of the building, which would provide for thirty extra patients and other necessary accommodation.

HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.—Last week the Lord Chancellor occupied the chair at the annual festival, held at the Hôtel Métropole. A large and influential company attended. Lord Halsbury, in proposing the toast "Prosperity to the Hospital for Sick Children," stated that it was the fortieth anniversary of the institution. In the past year 1247 in- and 20,112 out-patients had been treated. It was imperatively necessary that the wards should be enlarged, and the new building which was projected would be of the utmost service to the suffering poor. Its progress hitherto had suffered by what he would term the discussions between capital and labour. They only wanted £10,000, and he hoped it was not too much to expect that in such a cause the amount would be readily subscribed. The secretary announced subscriptions and donations to the amount of £4500.

PRESENTATION.—Mr. G. H. Butler, L.R.C.P.Irel., L.R.C.S. Edin., of Whitechurch, Hampshire, has been presented, on his leaving, after a residence of nearly seven years, by the inhabitants of the town and neighbourhood, with a testimonial, which consists of an illuminated address accompanied by a purse containing £60.

PREVENTION OF CRUELTY TO CHILDREN.—The Marchioness of Salisbury opened last week a new wing of Shelter at Harpur-street, Bloomsbury, in connexion with the work carried on by the National Society for the Prevention of Cruelty to Children. There are now three houses in that street occupied for the work, one house being utilised for offices and the other two for the accommodation of children, fifty of whom live on the premises.

POOR-LAW MEDICAL OFFICERS' ASSOCIATION.—At a meeting of the Council held at their rooms, 3, Bolt court, Fleet-street, on March 29th, it was resolved that a communication be addressed to Sir Walter Foster, M.P., and Dr. Farquharson, M.P., asking for their assistance to obtain an insertion of a clause in the "Coroners Act Amendment Bill" now before Parliament, declaring that workhouses are not meant to be included in medical institutions referred to in Clause 22, Subsection 2, of the Coroners Act, 1887.

UNIVERSITY COLLEGE HOSPITAL.—Dr. C. J. Hare presided at the annual meeting held last week. The chairman remarked that, though the expenses had not been covered, the report on the whole was satisfactory. The influenza epidemic had severely taxed the resources of the hospital. The increase in the number of in-patients was 512, and of out-patients and casualties, 3099. Referring to the need of rebuilding and enlarging the hospital, the report stated that a fund already existed for that purpose, and amounted to £13,000 towards the £30,000, the estimated outlay. The receipts for the year were £20,219 4s., while the expenses amounted to £23,344. The report was adopted.

MEDICAL NOTES IN PARLIAMENT.

The Influenza and School Attendance.

IN the House of Commons, on Thursday last, in answer to Sir J. M'Kenna, Mr. Jackson said: As I stated, in reply to the hon. and learned member for North Longford on February 26th, the Commissioners of National Education in Ireland invariably allow in all cases in which the school attendance is reduced owing to severe weather, prevalence of epidemic, or other exceptional cause, a reasonable time for the re-establishment of the normal average before proceeding to cancel the grant for an assistant.

Destructors in London.

Mr. Ritchie, answering Mr. Pickersgill, said that a clause was included in the Public Health (London) Act of last Session to provide a remedy in cases where premises are used by a sanitary authority for the treatment or disposal of house refuse in such a way as to be a nuisance or dangerous or injurious to health. In any such case proceedings for ensuring the abatement of the nuisance might be instituted by the County Council or any sanitary authority or person aggrieved.

Dublin Barracks Improvement Bill.

On Friday this Bill was read a second time, and referred to a Select Committee.

Alleged Medical Irregularity.

In the House of Commons on Tuesday, March 29th, Mr. Maden asked the Secretary of State for the Home Department whether his attention

Digitized by Google

had been called to an inquest, held on March 22nd, 1892, at the Islington coroner's court by Dr. G. Danford Thomas, on the body of Susannah Elizabeth Waller, aged seven months, the daughter of Herbert Waller, greengrocer, of 100, Palmerston-road, Finsbury-park; and whether he was aware that a certificate of death was given, signed by D. H. Dyte, L.R.C.P. Lond., M.R.C.S. Eng., and L.S.A. Lond., of 43, Poole's-park, who, it was proved, had not seen the deceased before her death; if so, what course of action the right hon. gentleman proposed to take.—Mr. Matthews: Yes, sir, I have received a report on this case from the coroner. The facts are correctly stated in the question. The coroner informs me that he has communicated with the Registrar-General in order that such legal action may be taken by that official as under the circumstances he may deem advisable. I may add that I have received a letter from Mr. Dyte, admitting that he had not personally seen the deceased, and expressing his deep regret for what had happened; but explaining that the child had been regularly attended by his assistant, who reported to him from time to time, and that he was only prevented from attending personally by severe injuries under which he was suffering at the time.

Water Bills in Parliament.

The Board of Trade have published their report on the Birmingham Corporation Water Bill, expressing the opinion that insufficient provision is made in the measure for the protection of the fishery interests of the river Wye. They purpose that the Bill should be amended in that and in some other respects. The Board also show themselves hostile to the works proposed in connexion with the Swansea Corporation Water Bill.

Coroners in Boroughs.

Sir A. Rollit obtained leave on Wednesday last to bring in a Bill to amend the law in relation to the appointment of coroners in boroughs, and it was read a first time.

Metropolitan Smoke Nuisance.

In the House of Lords, on Thursday, March 31st, on the motion to go into Committee on the Smoke Nuisance (Metropolis) Bill, Viscount Middleton thought the machinery would not work smoothly. The Marquis of Salisbury did not oppose the motion. The evil was great, and it would be an extreme step to ask the House to refuse a Committee stage. The motion was agreed to, and the Bill was considered in Committee.

University Education in London.

In the House of Commons on Thursday Mr. Bartley and Sir Albert Rollit addressed questions to the First Lord of the Treasury with reference to the proposed Royal Commission on University Education in London.—Mr. Balfour asked his hon. friends to repeat their questions on Monday, when he hoped to be able to give a full and complete statement on the subject.

Enteric Fever at St. John's Wood Barracks.

Mr. William Lowther asked the Secretary of State for War whether there had been any cases of typhoid fever amongst the officers at the St. John's Wood Barracks within the last three weeks.—Mr. Stanhope, in reply, said he regretted that Second Lieutenant Lord Sudley was reported on March 12th as sick of enteric fever. There did not appear to be any evidence that it was contracted in the barracks, and he was glad to say that the case was progressing favourably. These barracks had been recently carefully examined, and no insanitary conditions had been found.

Cork District Lunatic Asylum.

Dr. Tanner asked the Chief Secretary to the Lord-Lieutenant of Ireland if he would explain why the Board of Control in Dublin had objected to medical students visiting the Eglinton or Cork District Lunatic Asylum for the purpose of obtaining clinical instruction?—Mr. Jackson replied that neither the Board of Control nor the Board of Governors had interfered in any way with the visits of the medical students to the Cork District Lunatic Asylum. He had received information from the Resident Medical Superintendent of the Asylum, who said that no action had been taken to prevent students visiting the asylum. In fact, he said, he had only just finished his three months' course of instruction to the students.

Infectious Disease on Board Ships.

In reply to Dr. Tanner, who asked whether any, and, if so, what, regulations were in force with regard to cases of infectious disease rejected and sent ashore from emigrant and passenger vessels, after the inspection by the Medical Inspectors to the Board of Trade, of passengers by outward bound ships, Sir Michael Hicks Beach said that the matter was one rather for the local sanitary authorities under the Public Health Act, 1875, than for the Board of Trade. The Board's medical inspectors reported to the local authorities whenever (as in London, for instance) these authorities asked them to coöperate by doing so, and he had directed that they should in future report, whether requested or not. He understood that no complaint had in recent years reached the Board of Trade of any outbreaks of disease having occurred under the circumstances stated by the honourable member.

The Islington Health Officership.

Dr. Farquharson asked the President of the Local Government Board whether he was aware that the Islington Vestry had, contrary to its own by-law, appointed Dr. Wynn Westcott to the office of medical officer of health, Dr. Westcott having been, until March 2nd, a member of the vestry and of the public health committee; whether this appointment was made without previous advertisement, and against the votes of many members of the Board, including the chairman of the public health committee; and whether he will cause inquiry to be made before confirming the appointment.—Mr. Ritchie said he understood that the Vestry of the Parish of Islington had appointed Dr. Westcott as medical officer of health as a temporary arrangement for six months, and that he was a member of the vestry and of the public health committee of the parish until the 20th of February last, when he sent in his resignation. The by-laws of the vestry provided that no person should be eligible for election to any paid office under the vestry who was a vestryman within six months next before the election; but this by-law, it appeared, was suspended under another by-law, which allowed of such suspension if two-thirds of the vestrymen present voted for it. The appointment was made without previous advertisement, and forty-five members voted in favour of it and twenty-two (including the chairman of the public health committee) against it. He was in communication with the vestry in reference to the proposal to make an appointment for six months.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.

BEESLEY, A. J., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer of the Infirmary, West Derby Union.

BEHRENDT, M. R. J., L.R.C.P., L.R.C.S. Edin., has been reappointed Medical Officer of Health for the Scunthorpe Urban Sanitary District.

BENNETT, VIVIAN BOASE, M.B. (Lond. Univ.), has been appointed Assistant Medical Officer to the Walton Workhouse Hospital.

BINGLEYS, ERNEST HORSFORD, L.S.A. Lond., has been appointed House Surgeon to the Chichester Infirmary, vice S. B. De Butts, resigned.

CHALLENOR, H. S., M.R.C.S., has been appointed Medical Officer for the Second and Fourth Sanitary Districts of the Abingdon Union, vice Dixon, resigned.

COLLIE, ROBERT J., M.D., C.M. Aberd., has been appointed Divisional Surgeon to the New Station of the P Division of the Metropolitan Police at Catford.

CONNOR, F. G., M.B., C.M. Edin., has been appointed Medical Officer to the Lismore Hospital, New South Wales.

CRUISE, J. E. W., M.B., B.Ch. Irel., has been appointed Resident Medical Officer of the Grafton-street Hospital, Liverpool.

DEAN, H. P., F.R.C.S., has been appointed Assistant Surgeon to the London Hospital, Whitechapel.

D'EVELYN, ALEX. MCN., B.A., M.D. Univ. Dub., has been appointed Certifying Factory Surgeon for the Ballymena District, vice Abraham Kidd, M.D., deceased.

EDGINTON, R. W., M.D. Brux., M.R.C.S., has been appointed a Certifying Surgeon under the Factories Act, vice Carter, resigned.

ELLIOTT, R. H., M.B., B.Ch. Irel., has been appointed Resident Medical Officer of the Netherfield-road Hospital, Liverpool.

FORBES, ARMITAGE, L.R.C.P. Edin., L.R.C.S. Irel., has been appointed Government Medical Officer and Vaccinator for the District of Wardell, New South Wales.

GLOVER, L. G., M.B., B.C. Cantab., has been appointed House Physician to the Royal Hospital for Diseases of the Chest, City-road.

GOODALL, J. K., L.R.C.P., L.R.C.S. Edin., has been reappointed Medical Officer of Health for the Whittington Urban Sanitary District.

GRANT, DUNDAS, M.A., M.D., F.R.C.S. Eng., has been appointed Surgeon for the Throat and Ear to the West-End Hospital for Nervous Diseases.

HOLT, H. M., L.S.A., has been appointed Medical Officer for the Leavening Sanitary District of the Malton Union.

JAMES, W. E., M.R.C.S., L.R.C.P. Lond., has been appointed Medical Officer of Health to the Newport Union Sanitary Authority.

JAMESON, G. B., M.B., C.M. Edin., has been appointed House Surgeon to the Central London Ophthalmic Hospital, Gray's-inn-road.

JENKINS, E. J., M.D. Oxon., M.R.C.P. Lond., M.R.C.S., has been appointed Honorary Medical Officer of the Sydney Hospital, New South Wales, vice Pickburn, resigned.

MELLER, CHAS. BOOTH, L.R.C.P., M.R.C.S., L.S.A., L.M., has been reappointed Medical Officer of Health for the Eastern District of the Bridgend and Cowbridge Rural Sanitary Authority, and District Medical Officer and Public Vaccinator for the Bonvilstone District of the Cardiff Union.

MILLS, Y. HUBERT, F.R.C.S., M.B., has been appointed Surgical Registrar to the London Hospital, Whitechapel, vice H. P. Dean.

MITCHELL, J. T., M.D., C.M. Aberd., M.R.C.S., has been appointed Honorary Medical Officer to the Local Benevolent Asylum, Victoria, South Australia, vice Usher, resigned.

MORRISON, ALEX. THOMSON, M.B., B.Ch., B.A.O. (R.U.I.), has been appointed Medical Officer and Public Vaccinator for the Waddesdon District of the Aylesbury Union.

MURRAY, H. B., L.A.H. Dubl., has been appointed Medical Officer of the Parkes Hospital, Sydney, New South Wales.

NICOLSON, JOHN, M.D. Edin., M.R.C.S., has been appointed Public Analyst for the Shire of Benalla, Victoria, South Australia.

NOYES, A. W. F., L.R.C.P. Lond., M.R.C.S., has been appointed Specialist for Diseases of the Skin at the Alfred Hospital, Victoria, South Australia.

POULTON, BENJAMIN, M.R.C.S., has been appointed Lecturer on Surgery at the University of Adelaide, South Australia.

RICHARDS, J. S., M.D., B.S., has been appointed Resident Medical Officer to the Royal Hospital for Children and Women, Waterloo-bridge-road, vice J. M. Thorne, M.R.C.S., resigned.

SIMPSON, ALEXANDER, M.A., M.B., C.M. Aberd., has been appointed Second Assistant Medical Officer to the Lancashire County Asylum, Whittingham, Preston.

SINCLAIR, WALTER W., M.B., C.M. Aberd., has been appointed Junior House Surgeon to the Birmingham and Midland Eye Hospital, Birmingham.

SYMPSON, E. MANSEL, M.D., B.C. Cantab., M.R.C.S., has been appointed Surgeon to the Lincoln County Hospital.

WALLIS, F. C., M.B., B.S. Cantab., F.R.C.S. Eng., has been appointed Assistant Surgeon to the Metropolitan Hospital.

WESTCOTT, W. W., M.B. Lond., M.R.C.S., has been appointed, *pro tem.*, Medical Officer of Health for Islington, vice Tidy, deceased.

Vacancies.

For further information regarding each vacancy references should be made to the advertisement.

ASTON UNION.—Resident Medical Officer at the Workhouse, Erdington, near Birmingham. Salary £100 per annum, with furnished apartments, rations, washing, &c. (Apply at the Union Offices, Vauxhall-road, Birmingham.)

MANCHESTER SOUTHERN AND MATERNITY HOSPITAL.—Resident House Surgeon. Honorarium at the rate of £75 per annum.

METROPOLITAN HOSPITAL, Kingsland-road.—House Physician, House Surgeon, and Assistant House Surgeon, for six months. In addition to board and laundry expenses, the House Physician and House Surgeon will each receive a salary at the rate of £60 per annum.

NORTH RIDING ASYLUM, Clifton, York.—Second Assistant Medical Officer. Salary £100 a year. Board, apartments, washing, and attendance.

NOTTINGHAM BOROUGH ASYLUM.—Assistant Medical Officer. Salary £125 per annum, with apartments, board, and washing.

PADDINGTON GREEN CHILDREN'S HOSPITAL, London.—House Surgeon for six months. Salary at the rate of £55 5s. per annum, with board and residence.

ROTHERHAM HOSPITAL.—Assistant House Surgeon for six months. Rooms, commons (exclusive of alcoholic drinks), and washing will be provided.

SEAMEN'S HOSPITAL SOCIETY, Greenwich.—Visiting Physician for the Branch Hospital in the Royal Victoria and Albert Docks.

SEAMEN'S HOSPITAL SOCIETY, Greenwich.—Visiting Ophthalmic Surgeon.

SOUTH DEVON AND EAST CORNWALL HOSPITAL, Plymouth.—Honorary Assistant House Surgeon.

SUSSEX COUNTY ASYLUM, Hayward's-heath.—Junior Assistant Medical Officer. Salary £100 a year, with board, lodging, and washing.

TEIGNMOUTH, DAWLISH, AND NEWTON INFIRMARY, DISPENSARY, AND CONVALESCENT HOME.—House Surgeon (to act also as Secretary). Salary £40, with board, lodging, and washing.

THE RETREAT, York.—Junior Assistant Medical Officer. Salary £100 per annum, with board, lodging, and washing.

WANDSWORTH AND CLAPHAM UNION.—Assistant Medical Officer at the Infirmary of the Union. Salary £120 per annum, with apartments, board, and washing. (Apply at the Union Offices, New Wandsworth.)

WEST BROMWICH DISTRICT HOSPITAL.—Assistant House Surgeon. Terms: board, residence, and washing.

Births, Marriages, and Deaths.

BIRTHS.

BALLANCE.—On March 26th, at Harley-street, W., the wife of Charles A. Ballance, M.S., F.R.C.S., of twin daughters.

MATHESON.—On March 28th, at Gibson-square, N., the wife of John Matheson, M.A., M.D., of a son.

MARRIAGES.

BAIRD—BROWN.—On March 23rd, at St. John's Church, Devonport, Andrew Baird, Surgeon-Captain Medical Staff, to Florence Anna, widow of the late Charles J. Brown, of Brentwood, Essex.

HINGSTON—SMITH.—On March 23rd, at Grampound Church, by the Rev. R. Blackmoor, Vicar of Merther, and the Rev. C. H. Vivian, Rector of Creed, Richard Hingston, M.R.C.S. Eng., L.R.C.P. Lond., only son of Andrew Hingston, Surgeon, Liskeard, to Sarah Elizabeth (Bessie), elder daughter of Mr. G. W. Smith, Ventonwyn, Grampound.

SHAW—SPALDING.—On March 29th, at Argyle-square Church, King's-cross, Lauriston Elgie Shaw, M.D., of St. Thomas's-street, S.E., youngest son of Dr. Archibald Shaw, of St. Leonards, to May Howard, the eldest daughter of J. Howard Spalding, Esq., of Ealing.

DEATHS.

ALEXANDER.—On March 21st, at the residence of his son, Bethune-road, Stoke Newington, David Alexander, L.R.C.S. Edin., late of Lochee, Dundee, aged 81.

BOWES.—On March 23rd, at Pau, John Bowes, M.R.C.S., of Richmond, Yorkshire, aged 78.

CLARK.—On March 25th, at Blair Lodge, Minehead, Somerset, Dr. Thomas Clark, aged 53.

MINNS.—On March 25th, at White Hart-street, Thetford, Emily, beloved wife of Allan Minns, L.R.C.P. Lond., aged 32 years.

TOMKINS.—On March 27th, at West Leigh, Leicester, after influenza and pneumonia, Henry Tomkins, M.D. No cards.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Medical Diary for the ensuing Week.

Monday, April 4.

ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M., and on Tuesday, Wednesday, Friday, and Saturday at the same hour.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations daily at 10 A.M.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.

CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M.; Thursday, 2.30.

HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.

METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.

ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.

CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M., and each day in the week at the same hour.

UNIVERSITY COLLEGE HOSPITAL.—Ear and Throat Department, 9 A.M.; Thursday, 9 A.M.

ROYAL INSTITUTION.—5 P.M. General Monthly Meeting.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN (40, Leicester-sq., W.C.).—8 P.M. Mr. C. S. Tomes: Studies on the Growth of the Jaws. Casual Communications:—Mr. S. J. Hutchinson: A case of Necrosis and Fracture of the Lower Jaw.—Mr. M. Y. Woolf: A Tooth forced into the Antrum, and tolerated in that position for three years.—Mr. A. W. Barrett: The Electric Illumination of the Mouth for suspected Antral Disease.

MEDICAL SOCIETY OF LONDON.—8.30 P.M. Mr. J. Knowsley Thornton: Further cases illustrative of Hepatic Surgery.

Tuesday, April 5.

KING'S COLLEGE HOSPITAL.—Operations, 2 P.M.; Fridays and Saturdays at the same hour.

GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at same hour. Ophthalmic Operations on Monday at 1.30 and Thursday at 2 P.M.

ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.

ST. MARK'S HOSPITAL.—Operations, 2 P.M.

CANCER HOSPITAL, BROMPTON.—Operations, 2 P.M.; Saturday, 2 P.M.

WESTMINSTER HOSPITAL.—Operations, 2 P.M.

WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Consultations, Monday, 2.30 P.M. Skin Department, Monday and Thursday, 9.30 A.M. Throat Department, Tuesdays and Fridays, 1.30 P.M. Electro-therapeutics, same day, 2 P.M.

ROYAL INSTITUTION.—3 P.M. Professor V. Horsley: The Brain.

THE QUEEN'S COLLEGE, BIRMINGHAM.—4 P.M. Dr. Arthur Foxwell: The Condition and Treatment of the Vascular System in Chlorosis and other Debilitated States. (Ingleby Lecture.)

ROYAL COLLEGE OF PHYSICIANS (Examination Hall, Victoria Embankment).—5 P.M. Dr. Pye-Smith: Certain Points in the Etiology of Disease. (Second Lumleian Lecture.)

PATHOLOGICAL SOCIETY OF LONDON.—Mr. F. C. Abbott: Series of Congenital Dislocations of the Radius (four generations).—Mr. J. J. Clarke: (1) Litter of Kittens affected with Talipes and other Congenital Malformations; (2) Human Monster.—Dr. J. Adams: Ileo-colic Intussusception from Inverted Meckel's Diverticulum.—Mr. C. B. Lockwood: Polypus of Small Intestine associated with Intussusception.—Dr. G. Barling: Acute Double Tubercular Disease of Testes.—Dr. P. H. Pye Smith: Unusual Distribution of Secondary Cancer.—Mr. E. W. Willett: (1) Aneurysm of the Aorta in a Child; (2) Diphtheritic Membrane on the Stomach of a Child.—Dr. W. Edmunds: Cystic Disease of Kidney.

Wednesday, April 6.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.

MIDDLESEX HOSPITAL.—Operations, 1.30 P.M.; Saturdays, 2 P.M. Obstetrical Operations, Thursdays, 2 P.M.

CHARING-CROSS HOSTITAL.—Operations, 3 P.M., and on Thursday and Friday at the same hour.

ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour.

LONDON HOSPITAL.—Operations, 2 P.M.; Thursday & Saturday, same hour.

ST. PETER'S HOSPITAL, COVENT-GARDEN.—Operations, 2 P.M.

SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.

GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 1.30 P.M.; Skin Department, 1.45 P.M; Saturday, 9.15 A.M.

ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.

CHILDREN'S HOSPITAL, GREAT ORMOND-STREET.—Operations, 9.30 A.M. Surgical Visits on Wednesday and Saturday at 9.15 A.M.

OBSTETRICAL SOCIETY OF LONDON.—8 P.M. Specimens will be shown by Dr. Leith Napier. Adjourned Discussion on papers on Cæsarean Section by Drs. Leith Napier, John Shaw, and Cullingworth.—Dr. Lewers: Six cases of Craniotomy, with Remarks on the Relative Position of Craniotomy and Cæsarean Section.

Thursday, April 7.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M. Surgical Consultations, Wednesday, 1.30 P.M. Ophthalmic Operations, Friday, 1.30 P.M.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Ear and Throat Department, 9 A.M.

ROYAL INSTITUTION.—3 P.M. Dr. B. A. Whitelegge: Epidemic Waves.

CHELSEA HOSPITAL FOR WOMEN.—5 P.M. Dr. A. D. Leith Napier: Certain Clinical Relations of Gynæcology to Obstetrics.

ROYAL COLLEGE OF PHYSICIANS (Examination Hall, Victoria Embankment).—5 P.M. Dr. Pye-Smith: Certain Points in the Etiology of Disease. (Third Lumleian Lecture.)

HARVEIAN SOCIETY (Stafford Rooms).—8.30 P.M. Mr. F. W. Parsons: Notes of a case of Chronic Tubercular Phthisis.—Dr. T. Edward Squire: Pulmonary Affections which may lead to Phthisis.

Friday, April 8.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

CLINICAL SOCIETY OF LONDON.—8.30 P.M. Dr. Washbourn and Mr Arbuthnot Lane: Floating Kidney: New Mode of Nephrorrhaphy.—Mr. Littlewood: A case of Traumatic Cyst of the Pancreas successfully treated by Stitching the Cyst Wall to the Abdominal Parietes and Drainage, with an Analysis of the Pancreatic Fluid subsequently collected.—Dr. Hector Mackenzie: A case of Hydatid of Lung which proved fatal by rupture into a bronchus nine hours after Treatment by aspiration.—Mr. Stephen Paget: A case of Abdominal Section followed by Parotitis; recovery.

ROYAL INSTITUTION.—9 P.M. Prof. W. E. Ayrton: Electric Meters, Motors, and Money Matters.

Saturday, April 9.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; and Skin Department, 9.15 A.M.

ROYAL INSTITUTION.—3 P.M. Prof. J. F. Bridge: Dramatic Music.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and address of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

We cannot undertake to return MSS. not used.

"THE ETHICS OF TRUTH IN MEDICINE."

An Honest Doctor.—There is nothing in law or "ethics of truth" to prevent our correspondent adopting any opinions that commend themselves to his own judgment after due consideration. His conclusions may seem so unreasonable to others, who may think it impossible or undesirable to coöperate with him professionally, but there need be no loss of respect on either side. We have to express regret for delay in this reply.

H. G. D.—New River water is usually of excellent quality, and is seldom benefited by domestic filtration. A good filter should remove suspended matter, and above all should secure at the same time intimate contact of the water with an excess of air. Spongy iron, manganous carbon, pure animal charcoal, and kieselguhr are excellent filtering media. As we have often pointed out, coke is one of the best materials, but it requires long and continuous washing.

P. P.—It is something very like it. It is certainly not the ordinary case, condemned and punished repeatedly by the General Medical Council; but it is an approach to it that should not be practised by a registered practitioner.

F. H. R.—Zeitschrift für Hygiene.

EFFECT OF DISEASE ON THE EYELASHES.

To the Editors of THE LANCET.

SIRS,—I have a case in which the eyelashes of the inner half of the upper eyelid have become quite white. The lady having black hair, the effect is very conspicuous. She has not suffered from neuralgia, nor is there any assignable cause. I should be glad if someone having had experience of similar cases will suggest a remedy. I have painted the lashes with nitrate of silver, but without success.

I am, Sirs, yours faithfully,

March 23rd, 1892. A SUBSCRIBER.

Digitized by Google

"TOUTING" IN HALIFAX.

To the Editors of THE LANCET.

SIRS,—In your issue of March 5th you have a paragraph entitled "Touting with High Sanctions at Cambridge" (p. 365). I should like to draw your attention to a similar but worse example of "touting," but not with what can be considered as "high sanctions," at Halifax. I enclose you a handbill of the Halifax Provident Dispensary, such as is being left at the houses of patients of other medical men. At Cambridge they have at least a wage limit, which, as things go, is a pretty fair one; but at Halifax, as you will see, there is absolutely no wage limit at all. I may add that originally—i.e., at its inception—there were ten medical officers selected to act on the Dispensary staff, but seven of these resigned on the refusal of the committee to adopt a wage limit. The remuneration of the medical gentlemen is about one halfpenny per week per patient—a much smaller rate than a costermonger would expect to receive for his toffee at a stand in the street. A benevolent man giving gratuitous advice to a charitable institution, or relieving the suffering poor without fee or reward, is noble in the extreme; but when a member of our profession offers his services at such a low rate to an object which no one can call a charitable one, it is time that the Colleges interfered to prevent such modes of practice. The hard-working practitioner will then have a chance to make a living and uphold our once noble profession with all due decorum.

I am, Sirs, yours faithfully,

March, 1892. FAIR PLAY.

*** The following is the scale of charges, and this, be it understood without a wage limit. We cannot defend such a system.—ED. L.

Scale of Payments.

	Per week.	Entrance fee.
For any person under 14 years of age ..	½*d.*	0*s.* 6*d.*
For any person over 14 years of age	1*d.*	0*s.* 0*d.*
For an adult and one child under 14 ..	1½*d.*	1*s.* 3*d.*
For an adult and two children under 14 ..	2*d.*	1*s.* 6*d.*
For an adult and three children under 14 ..	2½*d.*	1*s.* 9*d.*
For a man and his wife	2*d.*	1*s.* 6*d.*
For a man, wife, and one child under 14 ..	2½*d.*	1*s.* 9*d.*
For a man, his wife, and all his children, under 14 years of age	3*d.*	2*s.* 6*d.*

DIABETES FOLLOWING INFLUENZA.

To the Editors of THE LANCET.

SIRS,—As an exceptional sequel of influenza, perhaps you will consider this letter of sufficient interest to publish in your valuable journal.

A young, robust corporal in the Royal Artillery was admitted to hospital on Dec 9th, 1891, suffering from influenza, from which he recovered. But on the eighth day after admission he reported that he passed a large quantity of urine at frequent intervals. The urine was therefore kept by the orderly, and it was discovered that he passed fourteen pints and a half in twenty-four hours, with a specific gravity of 1031. The patient was immediately placed upon a physiological dietary, and ordered pills containing codeia and asafœtida; he was also extra warmly clothed in flannel. At one period of the disease he passed seventeen pints of urine in twenty-four hours, and the specific gravity reached 1038. He gradually improved and gained weight, and was finally discharged from hospital convalescent on March 10th, 1892. He had been taking ordinary diet for a fortnight before he was discharged, and all medicine had been stopped. The etiology of this temporary derangement is obscure. No doubt congestion of both kidneys and hepatic organ simultaneously, due to chill or some subtle poison affecting the nervous system, and so perverting the normal excretions.

I am, Sirs, yours faithfully,

Dover, March 21st, 1892. J. HOYSTED.

CHEAP NOTIFICATION.

To the Editors of THE LANCET.

SIRS,—The Huddersfield Corporation allows only 1*s.* for certificates of infectious disease. This is according to by-laws of the Corporation passed before the Compulsory Notification Act. This, after paying the postage, leaves only 11*d.* for the certificate. Is it in the power of the Corporation to make a by-law to comp edical men to accept 1*s.* when 2*s.* d is the usual fee? If so, could Corporation exact the same service for a still smaller sum? am, Sirs, yours truly,

Huddersfield, March 17th, 1892. J. W. DRAPER.

*** The medical men should protest, and would have a good case with the fulcrum of the Compulsory Notification Act, which, however, we understand to be not in force in Huddersfield.—ED. L.

ORIGINAL WORK AND GENERAL PRACTICE.

To the Editors of THE LANCET.

SIRS,—Confessedly, there is much room for original work in our profession. Many general practitioners recognising this, with time at their disposal, would be very pleased to enter upon such work, but feel themselves handicapped by their inaccessibility to hospitals where, for most subjects, scientific methods can only be adopted and material for investigation found. A little guidance in the choice of work most suited to men so situated would, I feel sure, be welcomed by many, and to have your suggestions would be very helpful to others and

Yours truly,

Watford, Herts, March 28th, 1892. A MEDICAL PRACTITIONER.

"THE SPREAD OF SMALL-POX."

AN American correspondent questions the accuracy of the statements in the *Echo*, on which we lately commented, as to the spread of small-pox in Philadelphia being due to the landing of an immigrant in 1872. Our correspondent alleges that he lived in Philadelphia at the time, that there had been sporadic cases in the winter of 1869–70, and that there was an epidemic in 1870-71 and 1871-72. We cannot vouch for the statements which our contemporary quoted from the Consular Report of 1890, and which were too consistent with human experience elsewhere. We are obliged to our correspondent—Dr. George H. Clark.

F.R.C.P. (St. Leonards).—The question is not easily answered. There is no body whose duty it is to decide on the comparative conditions of membership of the respective Colleges, and we are not prepared with a short reply to so important a question. Theoretically there should be no territorial distinction between corresponding qualifications.

R. N. will see in THE LANCET of last week an answer to his first question. The reason for the action of the General Council in the case mentioned was fully set out in THE LANCET of Nov. 20th, 1886, p. 992.

Dr. Dockrell.—Our general rule is to follow the wishes of the contributor, so that the information referred to is inserted if supplied in the communication submitted to us, but not otherwise.

Mr. Geo. T. Wilkinson.—Dr. L. Phillips, Medical Institute, Edmund-street, Birmingham.

SMALL-POX AND FOOTBALL.

To the Editors of THE LANCET.

SIRS,—In last week's issue of your valuable journal, at page 775, there appeared an annotation under the above heading. It is therein stated that a certificate was published by the sanitary inspector for this borough to the effect that Batley might be visited without danger of infection. This does not truthfully state the facts. Our inspector was applied to, and he granted a certificate to the secretary of the Batley Football, Cricket, and Athletic Club. This certificate may have been published, but it certainly was not done with the sanction or knowledge of our inspector. The certificate, when it stated that Batley was free from infection, stated the truth; and at the date it was written there was only one infected house in the borough. The adverse criticisms on this certificate which have appeared in your columns and in the public press have been most damaging to the industries of this town. In all conscience we have had a serious epidemic, and as a consequence trade in all branches has severely suffered. But we are now free practically.—I am, Sirs, yours faithfully,

JOHN STEWART, M.B., C.M.

March 28th, 1892. (M.O.H. *pro tem.*)

"A QUESTION OF ETHICS."

To the Editors of THE LANCET.

SIRS,—In reply to "One of the Olden Time," it is only necessary to say that the communications of the medical attendants in the case in question were published in the interests of the patient, and with the full knowledge and approval of those nearest to her and entitled to act for her. Your correspondent has left out of his view the principle of "medical ethics" which forbids bearing false testimony against his brethren, whom he so unjustly accuses in this case of a breach of confidence. I am, Sirs, yours obediently,

March 28th, 1892. ONE OF THE MEDICAL ATTENDANTS.

*** We are certainly of opinion that it is contrary to medical ethics that details of a case should be published in the lay press, with the names and addresses of the medical attendants, even when quoted from a medical journal; but on the occasion referred to we do not see that the medical attendants in question were to blame.—ED. L.

"TREATMENT OF CRACKED LIPS."

To the Editors of THE LANCET.

SIRS,—Ordinary cases of cracked lips may be effectually dealt with by keeping them constantly smeared with "lip salve." The salve best for this purpose is made rather stiff, and without the red colouring matter usually added. The patient must carry a small box always with him, so that the application may be renewed as soon as the lips begin to dry. If there are deep cracks bordered by thickened epithelium, it is sometimes good practice to pare down the hard margins. As a dental surgeon I have seen a vast number of cases, and I can recall few which have not yielded to these simple measures.

I am, Sirs, yours faithfully,

March 26th, 1892. H. S.

To the Editors of THE LANCET.

SIRS,—In reply to "Medicus" in your issue of the 26th ult., I should suggest that, assuming he has tried all the ordinary methods of treatment, he should have recourse to excision of the "crack." This simple operation speedily effects the cure of this often troublesome complaint, and if care is taken not to remove too much of the surrounding tissue, no disfigurement results. The edges of the wound may be brought together by fine horsehair sutures, or, if the operator prefers, a small hare-lip pin may be used.—I am, Sirs, yours faithfully,

March, 1892. M.R.C.S. ENG.

PANCREATIC DIABETES.

ON this subject an important monograph has just been presented to the Accademia dei Lincei of Rome. Its author is Prof. Capparelli, and its title is "Studi sulla Funzione del Pancreas e sul Diabete Pancreatico." A committee of the Academy has been appointed to report upon it.

Mr. W. H. Waterfield.—The question is a legal one, but unless there is something in the contract authorising such a bold procedure on the part of the patient his chance of recovering such charges would, we imagine, be very slight. On the other hand, it seems an untenable rule that messages must be sent before 10 A.M. This could not be enforced in reference to an illness occurring later in the day.

F.R.C.S. would do well to defer settling in the place till after the deceased's practice has been disposed of, and not to compete with the successor by purchase for any of the appointments.

Mr. S. Paget.—Very soon.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

COMMUNICATIONS, LETTERS, &c., have been received from—Dr. Wallace Anderson, Glasgow; Mr. Anderson, Nottingham; Messrs. Arnold and Sons, West Smithfield; Mr. Atkinson, Sheffield; Messrs. Goulstonian Lectures

ON THE

CHEMICAL PATHOLOGY OF DIPHTHERIA COMPARED WITH THAT OF ANTHRAX, INFECTIVE ENDOCARDITIS, AND TETANUS.

By SIDNEY MARTIN, M.D., F.R.C.P.,

ASSISTANT PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL AND TO THE HOSPITAL FOR CONSUMPTION, BROMPTON; LATE PATHOLOGIST TO THE MIDDLESEX HOSPITAL.

LECTURE III.

THE specific action of the diphtheria products is brought into greater prominence when it is contrasted in parallel experiments with the chemical bodies found in anthrax and in infective endocarditis.

Infective endocarditis.—The case of infective endocarditis examined was under the care of Dr. Cayley at the Middlesex Hospital, and I performed the post-mortem examination when I was pathologist to that hospital. The history of the case may be briefly stated. The patient was a young unmarried woman, aged twenty-one years. The illness began eight weeks before death with pain in the left breast, and was characterised by wasting and intermittent fever during the six weeks' stay in the hospital. The temperature rose to 103° or 104°F. every day, and only once did shivering occur. The cardiac signs were those of double mitral disease. Four weeks before death the right brachial artery became plugged by an embolus, and three weeks before death the left femoral. Albuminuria occurred four weeks before death. At the post-mortem examination, twelve hours after death, there was chronic disease of the mitral valve, with fungating vegetation spreading over the endocardium of the left auricle, and ulcerated on the surface. The blood was imperfectly coagulated, and was lakey in colour. There was a recent embolus in the left middle cerebral artery, and older emboli (surrounded by organising thrombus) in the right brachial and left femoral arteries, while at the origin of the superior mesenteric artery there was a softening embolus. The right kidney showed two scars of old infarcts, and there were two caseated infarcts in the spleen. The spleen was greatly enlarged, dark, and congested. The liver was fatty, the kidneys fibro-fatty, and the lungs œdematous. This was, then, a case of ulcerative endocarditis not associated with abscesses or pyæmia. The mitral valve was examined microscopically and the blood and spleen chemically, while cultivations were made from the blood and from the vegetations on the mitral valve. Microscopically the mitral valve showed the fibrous thickening of chronic disease with recent vegetations capped by fibrin. A section of the free edge of the vegetations showed the fibrils of fibrin capping the thickened connective tissue containing collections of round cells. Along the free edge of the fibrin was a fringe of micrococci, very thick and invading the fibrin. Outlying clusters of the cocci were also present, and in some parts the micro-organisms were seen in groups in the tissue of the valve itself. In some parts of the valve the cocci were present in the valve tissue itself in the form of clusters. In this case, then, the micro-organism has for its culture medium the fibrin capping the vegetations.

Bacteriological examination.—No micro-organisms were found by making cultivations of the blood of the right ventricle. From the vegetations, with proper precautions, a pure cultivation was at once obtained of cocci with the same microscopical appearances as those seen in the valves—viz., they were cluster or staphylo-cocci, and not streptococci. Only one culture out of the five made showed any contamination; four were pure, and showed only the growth of the staphylococci. Without going further into the bacteriological procedure, this organism may be described as growing on agar in bluish-white opaque circular colonies, and on gelatine in a similar manner, but rapidly liquefying the medium. Microscopically it is a staphylococcus, forming clusters and not chains.

Pathological action.—This coccus does not produce pus when introduced under the skin of a guinea-pig or into the circulation of a rabbit. In a guinea-pig it produces a febrile disorder lasting over eleven weeks, accompanied by extreme wasting and ending in death. When injected into the circulation only a slight illness results, from which the animal recovers. When killed, no micro-organisms were discovered in the blood. The pathological effects of this micro-organism have yet to be completely worked out. I contented myself as a commencement in determining what sort of illness it produced in animals and whether it formed abscesses. The kind of illness produced, and the absence of abscesses when subcutaneously introduced, showed that it had the characteristics of the coccus found in the valves of the heart. Each case of infective endocarditis must be studied by itself, for the disease is by no means an entity. Some cases of ulcerated cardiac vegetations occur as part of a pyæmia proceeding from pelvic or other abscesses, where the primary infective agent appears to be the staphylococcus or streptococcus pyogenes. In others, again, no primary pus focus is found, but there are multiple abscesses due to infective emboli from the ulcerated valves. Other organisms, such as Friedländer's pneumococcus, may also possibly play a part in the disease. In the case under consideration, however, there was only one micro-organism, and that one not a pus former.

Chemical examination.—A chemical examination was made of the blood and spleen by the same methods I have already described. The result showed that the same two classes of products are present in the blood and spleen as in anthrax and diphtheria—viz., digested proteids or albumoses, and a non-proteid product, which when first separated and purified is strongly acid. The albumoses are proto- and deutero-albumose, chiefly the latter, indistinguishable by chemical reactions from the similar bodies we have already discussed. The final product is separated by alcohol and purified by precipitation with ether and treating with chloroform. It is an amorphous, yellowish-brown body, with a strongly acid reaction. The amount of the products is seen in the following table:—

In Infective Endocarditis.

	Albumoses.	Alcoholic Extract.
From blood	0·236 gramme	Trace
From spleen	6·705 grammes	1·29
Total	6·941 grammes.	

The large amount of albumoses and alcoholic extract present in the spleen is remarkable. Here, again, as in diphtheria and anthrax, the spleen is the repository and manufactory of the chemical poison.

Physiological action of the albumoses.—The physiological action of the albumoses was tested side by side with that of anthrax albumoses while the experiments on diphtheria were progressing, so that the animals could be compared. The albumoses of infective endocarditis are producers of fever and retard the coagulation of the blood. The effect of the intravenous injection of a dose of 0·122 gramme per kilogramme of body weight is with the anthrax albumoses a great rise of temperature, lasting for three days; with the infective endocarditis albumoses the fever produced is much less marked. With a larger dose (0·2 gramme per kilogramme of body weight) the fever in the case of the anthrax albumoses is not so well marked; while in the case of the albumoses of infective endocarditis it is more marked than with the smaller dose. With a still larger dose (0·3 gramme) the anthrax albumoses cause only a slight rise of temperature, succeeded by a fall and death in two hours; while the albumoses of infective endocarditis cause a moderate rise of temperature, which is continued for two days. The anthrax albumoses, therefore, are much more toxic than those from infective endocarditis. The fever produced by them is well marked with a small dose, but with larger doses it is less, and with a lethal dose it is very slight indeed. In the experiments just described there is no paralysis produced, but wasting is observed in some of the animals.

Alteration in Weight.

Dose per kilogrm. of body weight.	Anthrax albumoses.			Albumoses of infective endocardits.		
	Gain.	Loss.	Time after inoculation.	Gain.	Loss.	Time after inoculation.
0·122 grm.	200 grm.	—	28 days	—	90 grm.	16 days
—	—	—	—	80 grm.	—	28 days
0·2 grm.	—	530 grm.	12 days	100 grm.	—	11 days
—	—	80 grm.	102 days	652 grm.	—	102 days
0·3 grm.	Death in 2 hours			70 grm.	—	10 days
0·153 grm. (in 3 doses)	—	—	—	85 grm.	—	100 days
0·122 grm. (in 3 doses)	—	130 grm.	4 days	210 grm.	—	4 days
—	—	1020 grm.	42 days	—	—	—

These figures show that the anthrax albumoses produce a greater effect on nutrition than those of infective endocarditis. When multiple doses of these products are given, fever is produced but no paralysis, contrasting greatly with diphtheria products. The effect on the temperature of three doses of anthrax albumoses on successive days = 0·122 gramme per kilogramme of body weight, and of the albumoses of ulcerative endocarditis, also in three doses, = 0·153 gramme per kilogramme of body weight. A rise of temperature each day followed the injection, which was continued for one day after the last inoculation. The anthrax animal died in forty-two days, having lost two-fifths of its body weight, while the ulcerative endocarditis animal showed no loss of weight, and was killed on the fifty-third day. This last was an adult animal; a young animal injected with the same dose of endocarditis albumoses died on the third day after the last injection.

Post-mortem examination.—The post-mortem examination of the animals that died or were killed showed the absence of any pathogenous micro-organisms. A microscopical examination of the phrenic nerves and of the motor nerves was made, and revealed no morbid condition, no nerve degeneration such as was observed in the case of the diphtheria products. The contrast with diphtheria is therefore well marked. Fatty degeneration of the heart was found in some of the animals, especially those which had been inoculated with the anthrax albumoses, and the animal which had the largest single dose of the albumoses from infective endocarditis. This fact helps to explain the fatty degeneration of the heart following the injection of the diphtheria products. Occurring in the animals inoculated with anthrax and ulcerative endocarditis albumoses, it tends to show that the fatty degeneration is due to an effect on the nutrition of the heart by the albumoses circulating in the blood stream.

Tetanus.—The case of tetanus examined was under the care of Mr. Hulke at the Middlesex Hospital. It was a typical case of acute tetanus following a penetrating wound of the sole of the foot caused by a nail. The symptoms began the week after the accident, and death, which occurred ten days after the accident, was preceded by frequently repeated tetanic spasms. The post-mortem examination showed nothing definite. A chemical examination of the blood was made, and 0·5972 gramme of albumoses (chiefly deutero-albumose) was obtained with a small quantity of a body soluble in alcohol and precipitated by ether. The albumoses, when injected into the circulation of a rabbit in the dose of 0·143 gramme per kilogramme of body weight, produced, not a rise, but a fall of temperature on the day of experiment. For two or three days the animal was quite well, but it then began to waste, so that on the twelfth day it had lost one-sixth of its body weight. It died on the twenty-first day, having lost nearly one-half of its original weight. This progressive wasting brings the tetanus albumoses into relation with those found in diphtheria. The completion of this subject I must leave for the present.

GENERAL CONSIDERATIONS.

Having now brought forward the facts in the chemical pathology of the infective disorders—diphtheria, anthrax, and ulcerative endocarditis—chosen for investigation, it is necessary to consider generally the bearing of the results. In summing up the effect on the body of the introduction into it or upon it of a primary infective agent, the symptoms may be referred to two causes—(1) mechanical, (2) chemical. The mechanical effects are illustrated by the fact that the infective agent may, as in diphtheria, produce a membrane which spreads down the air passage and endangers life. The effect of this mechanical obstruction—which is to some extent relieved by intubation or tracheotomy—is well recognised as a danger in diphtheria. Another example of mechanical effect is seen in infective endocarditis, in which not only do the fungating vegetations interfere with the proper action of the heart, but the emboli broken off from them, by plugging large vessels, cut off or diminish the blood-supply to a part, and so lead to grave results. Although such mechanical effects may be looked upon as merely pathological accidents, their consequences have to be considered in dealing with the pathology of these diseases. They sink, however, into comparative insignificance when the *rôle* of the chemical products of the primary infective agent is elucidated. What has been made clear to me during the course of the research, and what I have attempted to bring before you, is that these chemical products are specific in their action; that inasmuch as the bacillus anthracis is separable from other pathogenous micro-organisms as producing a definite disease (anthrax), so are the chemical products of the bacillus separable to a certain extent chemically, to a greater extent physiologically, from those formed by other pathogenous micro-organisms. Similarly with diphtheria, the bacillus diphtheriæ produces products differing in their physiological action from those found in anthrax and in infective endocarditis. The specific primary infective agent produces, therefore, specific chemical products by means of which it acts. It is evident from this that we have another basis for the study of infective disorders, in addition to the purely bacteriological one which is the study of the primary infective agent. The following now well-known bacteriological rules are recognised to prove that a particular micro-organism is the cause of a disease: (1) It must be found always associated with the disease; (2) it must be separated from the diseased tissues in pure culture; (3) it must be injected into susceptible animals, and reproduce the disease; (4) it must be again obtained from this experimentally produced disease. To this I would add another—viz., that the chemical poison must be obtained from the tissues in the natural disease, and products with a similar physiological action proved to be formed by the primary infective agent when grown outside the body. This will no doubt aid progress in pathology; because in some instances, as in cholera and leprosy, animals susceptible to the disease are not forthcoming. If, for example, it be definitely proved that certain chemical poisons with a specific action are present in the bodies or evacuations of cholera patients, and if the vibrio choleræ asiaticæ produces the same products, then we must look upon this micro-organism as the cause of the disease. It is possible that in some infective disorders, such as measles, scarlet fever, and small-pox, in which the primary infective agent is as yet unknown, a chemical examination of the tissues on the lines laid down may aid in the discovery of the living contagion. In this way, too, it will be possible to decide whether such a disease as has been described as membranous croup of the larynx really exists. There is no evidence at present that there is any disease other than diphtheria which can produce a false membrane in the larynx. And now that it is definitely known that diphtheria is a disease caused by the bacillus diphtheriæ, and that the chemical substances found in it are readily recognisable by the fact of their producing a definite nerve lesion, it will be possible for any observer who has a case of membranous croup under observation to separate the chemical substances from the "croupous" membrane, or from the body after death, and to decide their nature. I should like to insist on the point that, in studying the chemical pathology of an infective disorder, it is not sufficient to investigate the artificial chemical products of the primary infective agent; a chemical examination of the tissues of persons dead of the disorder must also be performed. The great importance of this is shown by one fact which has been brought out in these experiments—viz., the pathological *rôle* of the spleen.

Rôle of the spleen.—The spleen is an organ with an obscure physiology and a still obscurer pathology. Anyone who has tried to understand what has happened to a spleen in a case of infectious disease must have been struck with the utter hopelessness of coming to any definite conclusion regarding that organ from a merely physical examination. From the physiological point of view, it is known to undergo certain mechanical changes which can

Digitized by Google

only be of slight import, and (besides being a birthplace for white blood cells) to contain in comparatively large amount the crystalline products of the breaking up of proteids, such as uric acid &c. The chief point about the organ, however, from a pathological point of view, is that the blood flows through the walls of the vessels into spaces; then we have a more or less stagnating fluid, the proteids of which can be digested either by micro-organisms or by ferments. In anthrax and infective endocarditis this organ is greatly enlarged; in diphtheria it is usually normal in size. In all three cases it is the proteids of the spleen from which the specific poisonous products are mainly formed; they serve as the food of the infective agents, primary or secondary.

Food for the infective agents.—Besides the spleen, there are other parts of the body in which the primary infective agent finds suitable media in which to grow. Thus pathological effusions, whether already present in the body or formed by the primary infective agent, are suitable culture media. These effusions, speaking generally, may be considered as slightly alkaline solutions of proteids which are outside the active metabolism of the body—i.e., the proteids are not in a living fluid like the blood. The bacillus anthracis, for example, when injected under the skin of an animal forms this effusion by its products, and thus provides its own culture medium. The interstitial fluids of the tissues of the body, containing as they do the amount of proteid, sodium chloride, and phosphates necessary for the growth of the primary infective agent, probably serve as culture media. Lastly, in diphtheria and in infective endocarditis, fibrin serves as the medium in which the micro-organism flourishes. In diphtheria the false membrane is composed of fibrin, which, as I have shown, is in a state of digestion, and the exudation of this fibrin is no doubt produced by the earliest products of the bacillus diphtheriæ. In the case of infective endocarditis which I have brought before you, the nidus of the micro-organism was formed by the fibrin capping the vegetations. Without a suitable medium the primary infective agent cannot develop, cannot produce its poisonous products.

Products formed by the primary infective agent—I have attempted to make clear the fact that in these infective disorders the primary infective agent or living contagion produces its effect in man by means of its specific chemical products, which it forms from the proteids of the body with or without the intervention of a ferment. It may be that in all cases the chemical substances are produced by means of an unorganised ferment excreted by the primary infective agent; but the point that concerns us is that in only one of the diseases examined—viz., diphtheria—is there any evidence to show that this ferment plays a direct pathological *rôle*. In this disease, in which the bacillus diphtheriæ is limited to the superficial parts of the membrane, and does not diffuse itself throughout the body, it was seen that there was something excreted by the bacillus and absorbed into the body, in the tissues of which were digested products. This excretion of the bacillus was looked upon as a ferment, and was called the "secondary infective agent." In anthrax and infective endocarditis, on the other hand, the primary infective agent is in the body itself, and there is no evidence that a ferment plays any direct part in the causation of the symptoms of the disease. I very much suspect that in tetanus, a disease which resembles diphtheria in the fact that the primary infective agent is limited to the site of inoculation, a ferment or excretion of the bacillus acts as a secondary infective agent. But this is quite undecided. The secondary infective agent cannot be expressed in any chemical terms: only in terms of what it can accomplish, either (1) of its physiological action, or (2) of its capacity for forming from proteids chemical bodies which resemble it in physiological action. The secondary infective agent is one possessing properties which, like those of unorganised ferments, are usually expressed by the term "vital"; it is, as it were, one of the vital properties of the living cell cast off in a form which is unorganised.

Products of the infective agents, primary and secondary.—The products of the primary or secondary infective agents are chemical bodies belonging, as I have shown, to two groups, a proteid and non-proteid. The proteid form the class of digested proteids or albumoses and peptone; the second group are final products from the digested proteids and are analogous to the leucin and tyrosin of pancreatic digestion. The organic constituents of the body consist of proteids, carbohydrates, fat, and certain so-called extractives, which, like urea, uric acid, &c., are nitrogenous and the result of proteid metabolism. There is no evidence at present that pathogenous micro-organisms can form from fats and carbohydrates poisonous bodies; they may break them up, but the chemical bodies produced have little physiological action, while the proteids are substances which, from their enormous molecule and from the presence of nitrogen, are capable of being split up into poisonous bodies. The chemical difficulty with proteids is that there is no knowledge of the size of their molecule and, what is of great importance, of their molecular construction. The percentage composition gives no idea of the size of the molecule, and the only idea we have of the molecular constitution of a proteid is from a study of the chemical constitution of the nitrogenous bodies resulting from its destruction. It is not, therefore, surprising that with regard to the first class of poisonous products under consideration—viz, the albumoses—no very definite chemical knowledge is forthcoming, and that, as I have stated, all the albumoses I have been describing give the same chemical reactions. An ultimate analysis to determine the percentage composition is of little value in the case, as it is the molecular constitution we wish to know. We have, therefore, to express the albumoses in terms of their physiological action and to be content with demonstrating that the diphtheria albumoses differ from peptic albumoses and those found in anthrax and in infective endocarditis, in producing a paralysis consequent on a nerve degeneration, and that the anthrax albumoses are more poisonous than those of infective endocarditis.

The chemistry of the final products.—The anthrax base, the organic acid in diphtheria &c., is, however, a subject which will probably yield very fruitful and definite results. Such an investigation is, perhaps, one of the most difficult in organic chemistry. For us, as physicians and pathologists, the physiological action of such substances is of more importance than their chemistry; but as they are factors in disease and in some diseases the chief factors, the more complete our knowledge of them, the more likely will the means be found to combat them. In anthrax, for example, it is the final product, the alkaloid, which is the cause of death—the albumoses play a very subsidiary part in the production of the fatal result. In diphtheria, on the other hand, the albumoses play the more important *rôle*, while the organic acid has only an insignificant action. There may, indeed, be other diseases in some of which the albumoses play the chief pathological *rôle*, in others the final product, whether base or acid.

Comparison with other poisons.—These poisons found in infective diseases do not stand alone; they are related to others found both in the vegetable and animal kingdoms. Albumoses (which I have called phytalbumoses) are widely spread in vegetable tissues; they exist in the seeds, and probably other parts of plants. Alkaloids or bases are also obtained from plants, and it appears to me a very promising field of research to determine whether the vegetable alkaloids are associated with digested proteids—whether, in fact, the vegetable cell produces, like the bacillus anthracis, two classes of products, the albumoses and a base. This is, however, a question for the vegetable physiologist. In some seeds (abrus precatorius and ricinus communis) there are proteids which have a distinct and powerful poisonous action. In the jequirity seed, for instance, there are, as I have shown, two poisonous proteids, a globulin and an albumose, both of which produce in very small doses a general disease, two of the features of which are the production of ecchymoses and the occurrence of sanguineous diarrhœa. The jequirity proteids resemble in many respects those of snake venom, and are like the albumoses of diphtheria and of infective endocarditis in producing a watery diarrhœa. I think, indeed, that the jequirity poison more closely resembles the secondary infective agent in diphtheria than any other poison I know, as it partakes of the nature of a ferment in its ready destruction by heat. Whether it produces a peripheral nerve degeneration or not I do not know.

Summary of the action of the poisonous products in infective disorders; effect on the blood and on nutrition.—One of the effects common to many of these proteid poisons is their power of preventing or hindering coagulation of the blood. This we have seen to be the case with the diphtheria albumoses, the effect of which in this respect is well marked, and lasts a long time after they have been injected

Digitized by Google

into the circulation. The albumoses of infective endocarditis also have this power, which is likewise possessed by the albumoses of peptic digestion, by the jequirity poison, and by many kinds of snake venom. This action shows that these poisons have a profound effect on the blood, and may account for the grave defects in nutrition which have already been described. The animals poisoned with the diphtheria or anthrax albumoses go on wasting after the fever has subsided, the loss of weight being greatest in the case of the diphtheria products, and proportional to the dose of the poison given. Tetanus albumoses may be classed with diphtheria as producing great wasting; while anthrax albumoses are less effective in this respect, and those of infective endocarditis least so. In connexion with this, there is the fatty degeneration of the cardiac muscle which has been shown in these experiments to follow the injection of not only the diphtheria products, but also, although to a less extent, the albumoses of anthrax and of infective endocarditis. There is no definite evidence that cardiac degeneration is directly dependent on a nerve lesion, either central or peripheral; and the fact that it is well marked after the injection of the anthrax albumoses which produce no degeneration in the nervous system points, in my opinion, to the conclusion that it is to the change in the blood which these poisons bring about that we must ascribe the fatty change. This fatty degeneration may, indeed, be only the final result of the poisons being special cardiac poisons. The skeletal muscles do not become fatty like the heart, unless there be nerve degeneration, as in diphtheria.

Effect on the body temperature.—From the experiments which have been described it is clear that the proteid products (albumoses) of the primary infective agents have a profound effect on the body temperature. Ott and Calmar first showed that ordinary peptic albumoses caused a rise of body temperature, and several observers have at various times investigated the effect of injecting into animals "septic material" freed from micro-organisms. These last experiments were performed at a time when the chemical characteristics of the products of pathogenous micro-organisms were unknown. The time has passed by for using impure material for physiological experiment. The most typical effect on the body temperature is seen in the case of the anthrax albumoses. A medium dose produces a rapid and high rise and a continuation of the fever for some days, a larger dose produces a less pronounced rise and a shorter duration of the fever period, while a still larger dose causes only a slight rise of temperature and a sudden fall, ending in death. The albumoses of infective endocarditis are less active in producing fever, while those of diphtheria and tetanus may be classed together, inasmuch as in medium doses they produce a fall of temperature. Diphtheria albumoses will produce fever, while those of tetanus, as far as has been ascertained, produce only a depression of temperature. It is a noticeable fact that it is the albumoses or proteid products of the infective agents, and not the final products, whether base or acid, that have the effects on the blood, on the temperature and on nutrition, that have been described.

Effect on the nervous system.—Many of these poisons select the nervous system for their action. One of the features of the action of albumoses is the production of coma, and in anthrax this coma is the special action of the base or alkaloid. Coma is a feature of jequirity and of snake poisoning. The final action of the albumoses in diphtheria is the production of coma, but their special action is to produce a paralysis dependent on nerve degeneration. It is quite possible that other products from diseases will be found to produce a peripheral palsy. The effect on the respiration which is observed in snake poisoning is ascribed to the action of the poison on the central nervous system, and when working at jequirity I came to the conclusion that its action on the respiration was also central. In diphtheria, however, where there is peripheral degeneration of the phrenic nerve, it is difficult to say how far the respiratory attacks are dependent on the peripheral degeneration, and how much they are due to an effect on the centres of respiration. Apart from mechanical obstruction, dyspnœa is one of the features of diphtheria in its acute stage, and it is possible that it may be due to an effect on the central nervous system; but here, again, it is difficult to exclude a peripheral action on the phrenics, for, as I have shown, the diphtheria products are special nerve poisons, and they may cause degeneration of the nerves even during the short course of the acute disease.

Question of immunity produced by the chemical products.—There is one question which I have left untouched—viz., that of the conferring of immunity against the disease by the means of its chemical products. This is, of course, an important effect. We have been considering the chemical products of an infective disorder or of the primary infective agent as specific in reproducing when injected into animals the symptoms of the disease. But it is evident that, if the chemical products are capable of protecting an animal against the invasion of the primary infective agent, this action must be essentially a specific one. For example, we could not suppose that the chemical products of anthrax would protect against diphtheria, or those of diphtheria against anthrax, but that only the products of anthrax could protect against the invasion of the bacillus anthracis. I wish to speak of the matter only in a general manner. I am, however, not at all sure that in all diseases there is this protection; I cannot conceive how the products in diphtheria could protect against the acute disease. In discussing the chemical products formed by the primary infective agent outside the body or in the natural disease, I have not mentioned any substances except those that are effective in producing the symptoms of the disease. There are some who have considered that such chemical products may consist of a "vaccine" and a "toxine." There is not the slightest evidence of this. There is no evidence of the existence of any chemical "vaccine" separable from the chemical "toxine," and I need, perhaps, hardly point out that such a "vaccine" has never been isolated. It was a term invented to explain phenomena which were not properly understood. There is also no evidence that there is any particular chemical substance which stops the growth of a pathogenous micro-organism. When grown in a flask it will not develop indefinitely, and it stops not because there is an anti-toxine formed, but because it is choked by its own chemical products in the same manner as peptic or tryptic digestion may be inhibited by the accumulation of the digested products.

In bringing these lectures to a conclusion I wish to say that the work was done for the Local Government Board, and to express my thanks to the medical officer for granting me permission to bring the subject before this College.

PULSATIONS AND MURMURS IN THE GREAT VEINS OF THE NECK:

THEIR PHYSIOLOGICAL AND CLINICAL SIGNIFICANCE.

By SYDNEY RINGER, M.D., F.R.S.,
AND
HARRINGTON SAINSBURY, M.D., M.R.C.P.

(*Concluded from page 741.*)

WE will now pass at once to consider certain characters belonging to venous murmurs heard at the root of the neck—characters which we have not examined in the preceeding sketch. The venous bruit, as heard in the internal jugular, has for the most part the character of a continuous bruit—i.e., the whole of the cardiac cycle between two succeeding beats of the carotid is filled up with a humming, or cooing, or purring sound, but if carefully listened to it is possible in most cases, and easy in many, to recognise that the sound varies in intensity; and that the variations follow each other in a sequence, which, on further investigation, is found to be of double rhythm—respiratory and cardiac. The respiratory rhythm shows a remission of the bruit during each expiration, an augmentation during each inspiration. The explanation of this phenomenon is not far to seek, for each inspiration facilitates the flow of blood into the chest, each expiration impedes it. The other sequence, of cardiac rhythm, concerns us chiefly, and we think that on the whole it is the more easy of recognition and the more common of occurrence. It shows two augmentations and two remissions during each cardiac cycle. What may be their explanation? The first step towards answering this is to time the phases of the bruit, and with a little care we succeed in this, and find that one augmentation falls in with the ventricular systole, the other with the ventricular diastole. It will be found most con-

PULSATIONS AND MURMURS IN THE VEINS OF THE NECK:

THEIR PHYSIOLOGICAL AND CLINICAL SIGNIFICANCE.

By SYDNEY RINGER, M.D., F.R.S.
AND
HARRINGTON SAINSBURY, M.D., M.R.C.P.

(Concluded from page 711.)

We will now pass at once to consider some
racters belonging to venous murmurs heard o
of the neck—characters which we have put
in the preceding sketch. The venous hum
the internal jugular, has for the most part
venous bruit—i.e., the vibr
ing beats of

venient to time the phases of the venous bruit by means of the pulse in the carotid of the opposite side of the neck. The remissions are sometimes so marked that the augmentations are heard as a double bruit; sometimes, indeed, especially in some postures, the murmur is actually double, there being a complete intermission.

The posture which favours intermission of the bruit is the recumbent. In many cases of anæmia it is possible, by making the patient lie quite flat, to convert the continuous bruit into an intermittent one. The mode of production is evidently the removal of the factor gravity. As a whole, the bruit is more faint in the recumbent position, and it may disappear altogether. What statements do we already possess concerning the remittent character of the venous bruit? We refer to a remission of cardiac rhythm. Hope[1] described the venous bruit as continuous if arterial pulsation were slight, as discontinuous if it were forcible. The bruit in the latter instance showed systolic exacerbations, and the explanation given by Hope was that this was due to the superaddition of the arterial whiff to the continuous venous murmur. He maintained that he could distinctly hear the arterial bruit through the venous sound, recognising the former by its higher pitch. We have no doubt that his explanation will hold good of some cases, and that, especially if rather heavy pressure be used, the arterial whiff may associate itself with the venous bruit and appear as an exacerbation; but we are equally certain that in the majority of cases the systolic element belongs to the vein alone, and the decisive proof of this is to be obtained by compressing the vein above, the murmur ceasing at once. Parrot[2] described the venous bruit as a *bruit à double courant* (p. 656), and he says (p. 664) that most authors have analysed the bruit (venous) into two parts. According to him, one augmentation falls in with the ventricular systole, which, as he points out, coincides in time with the auricular diastole. This murmur he regards as a direct bruit occurring during the flow towards the heart. The other bruit (or augmentation) he makes presystolic, and he regards it as a bruit of reflux due to the auricular contraction. Parrot's observations referred to the venous bruit of health or of anæmia. Bamberger's cases[3] are pathological cases with dilated right heart and probably insufficient tricuspid; they do not apply here, but we may mention one case in which a rough systolic bruit and a weak diastolic bruit were heard over the veins of the left side of the neck, because of Bamberger's remark that he was struck since he had never heard a diastolic venous bruit.[4] Friederich,[5] who also limited himself to pathological cases, seems to confirm Bamberger's remark as to the rarity of a diastolic venous bruit, since he mentions only two cases of such—viz., one of Graves' disease and one of aortic regurgitation, and explains them in an exceptional manner. Walshe[6] states that the venous murmur may be remittently continuous, "undergoing reinforcement and weakening at regular intervals," but he does not discuss the time of these reinforcements.

Of more recent authors we find that Balfour, describing chlorosis,[7] says: "The venous murmur is continuous and audible both during systole and diastole, its intensity increasing with the thoracic and cardiac aspiration, and diminishing with expiration and the cardiac systole, so that the venous hum swells and dies as these alternate." He thus describes the double, respiratory, and cardiac rhythm of the venous bruit, and since the venous hum is said to lessen with the cardiac systole, it must augment during the diastole; he describes therefore a diastolic exacerbation. Gee[8] speaks of the venous bruit as subject to rhythmical increase of loudness both during the inspiratory draught from out of the veins and during the ventricular systole—i.e., during the auricular diastole. Guttmann[9] says the venous bruit is increased during ventricular diastole, and should be diminished during systole, but that the systolic decrease is not only not demonstrable, but that an actual systolic increase is audible. This systolic increase he explains like Hope—viz., as due to the superaddition of a carotid whiff. Landois[10] describes the venous bruit as rhythmically increasing during the diastole of the heart or during inspiration.

These references may suffice to show that no definite settled teaching prevails as to the time of the phases or exacerbations of the venous bruit. Limiting ourselves to those of cardiac rhythm, these are recorded as systolic or as diastolic, or as both systolic and diastolic; in the latter case one augmentation occupies a special portion of the diastole—viz., the presystole. It is Parrot who says that the venous bruit is systolic and presystolic, and who adds that most observers have analysed it into two parts. Whether this is the fact or not—viz., that most authors have so analysed it,—we are in complete accord with him that the bruit shows a double element, and that its rhythm is systolic and diastolic; but we differ from him in making the diastolic augmentation follow instead of precede the systole. Perhaps one element of confusion has been the presence of a respiratory rhythm as well as of a cardiac rhythm, for it is clear that the opposing influences of inspiration and expiration must at one moment assist, at another hinder, the cardiac influences, according as an expiration or inspiration happens to coincide in time with systole or diastole. This objection is to be eliminated by suspending the respiration, but then a permanent obstacle is placed in the way of the venous current, and, according to Guttmann, the diastolic element of the venous bruit often becomes under these circumstances more faint, or actually disappears. In timing the phases of the venous bruit we have, however, made the patient hold the breath, and we maintain that even under these conditions it is possible in the majority of cases to determine a double rhythm, and that this is systolic and diastolic. We would again accentuate the point that actual intermission of the venous bruit is in many cases to be obtained by making the patient lie flat. The rhythm is thus more easily analysed. Will this observation, which we claim to be a matter of fact, fit in with physiological data? During the cardiac cycle there will be two points of time when the venous blood will find readiest access to the heart cavities: the first will be at the moment of ventricular systole, for this moment coincides in time with the *diastole* of the auricle which has just emptied itself into the ventricle; the second will be at the moment of ventricular diastole, for at this moment the distended auricle will be able to unload itself into the flaccid and empty ventricle. Nay, more, if the teachings of physiology be sound as to the development of a negative pressure in a cavity at the moment of relaxation, we shall have a suction force accelerating the flow into auricle and ventricle.[11] Be this as it may, there will be in any case least obstruction to the venous inflow at the commencement of ventricular systole and the commencement of ventricular diastole.

Discussing the pulsations of the veins of the neck, we have shown that in health and in anæmia there is no reason to believe that the blood current is reversed at any moment of the cardiac cycle; but that, on the contrary, the flow is always towards the heart, now more slowly, now more quickly. It is at the moments of quicker flow that the conditions for fluid vibration will best obtain, and hence whilst the continuous flow in one direction should manifest itself as a continuous hum, there should be, on *a priori* grounds, both systolic and diastolic augmentations of the same. Parrot's view of a reversal of the blood current in the presystole, due to the auricular contraction, is wholly unproved for quiet states of the circulation in health and in anæmia. But what about pathological states when, for instance, the right heart is overloaded through disease in the left heart or in the lungs? Here there is permanent overfilling of the great veins near the heart, and under these conditions we have seen that a pulsation in these veins due to actual back-flow from the full right auricle may obtain during the auricular and the ventricular contractions (presystolic and systolic). The pulsation, the systolic certainly, may be accompanied by a bruit, which will be caused by a regurgitant fluid vein; it was to this bruit that Bamberger drew attention. Does the distended right auricle ever

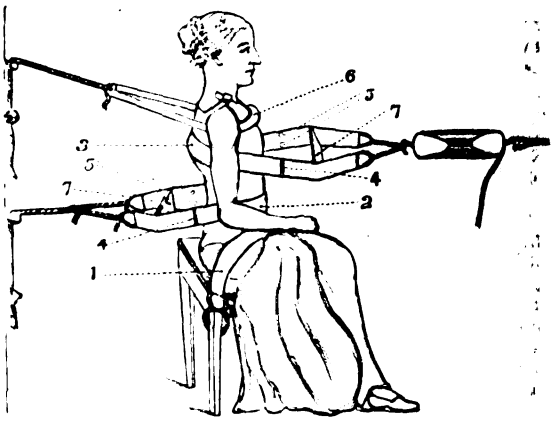
[10] Lehrbuch der Physiologie des Menschen, 1889, p. 187.
[11] According to this view the ventricular negative pressure would far exceed the auricular negative pressure, and therefore the diastolic bruit should exceed the systolic in force.

Digitized by Google

throw back its blood with sufficient force to create a bruit? We have not met with such a case, though theoretically it is of course possible.

In conclusion, let us point out that in quiet states of the circulation in health and in anæmia the continuous venous hum shows augmentations, systolic and diastolic, produced by accelerations of the onflowing blood; that at times the bruit may be actually discontinuous with systolic and diastolic phases, which again represent accelerations in the onflowing blood. Note, as characteristic of this, as we may term it, normal circulation that the *systolic augmentation* corresponds with the *collapse*, the *emptying of the vein*; that in pathological states marked by a *full right side* of the heart and distended veins a systolic venous bruit may be heard due to a wave of back-flow. Note, as characteristic of this abnormal state, that *this bruit* corresponds with the *systolic pulsation*, the *filling out of the vein*.



ON A METHOD BETTER THAN SUSPENSION OF APPLYING A PLASTER JACKET.

By RICHARD BARWELL, F.R.C.S.,
CONSULTING SURGEON TO CHARING-CROSS HOSPITAL.

CERTAIN drawbacks and inconveniences are connected with suspension of the patient while applying a plaster-of-Paris jacket; of these may be more particularly selected painful pressure on the jaw and occiput, as well as on the axillary plexus of nerves. The object of suspension is to straighten out the abnormal curve of the spine, so that the jacket when complete may be straighter than the unsupported back of the erect patient, thus preventing intervertebral pressure, and by successive applications correcting, as far as possible, the kyphosis or hump which must result if, such means being omitted, the diseased vertebræ synostose. Children, therefore, whose pelves and lower limbs are small and light, obtain little or none of such benefit; while adults with heavier lower developments may gain more temporary rectification, but can bear the pressure on the points of suspension a commensurately shorter time. Hence the plaster must be of such a quality as will set quickly; no gum or other colloid must be combined with it. The jacket must be completed with great rapidity, and not infrequently the patient must be taken down before hardening is so perfect as to obviate cracking and yielding; for, of course, when suspension ceases there is a tendency to recurrence of the curve, which a hastily applied jacket is too weak to resist. Much experience and practice may up to a certain point minimise these evils, but cannot eliminate them.

I have therefore for some years past ceased to employ suspension in kyphosis, and have straightened, as far as safety will permit, the patient's spine by a modification of my method of rachilysis, which, used differently, has proved successful in lateral curvature; the force—viz., traction by a system of pulleys—being used while the patient is sitting. It is thus carried out in a case of dorsal kyphosis: The patient being clothed in a skin-tight knitted vest, and with the usual parts padded, sits on an ordinary office stool about two feet and a half high, between two opposing walls in which certain hooks &c. are fixed, as for rachilysis. A three inch wide piece of webbing, with strong cords at each end, is secured to one of the back legs of the stool, and, passing over the top of the patient's thighs sufficiently tightly, is also secured to the other back leg (1). A strip of moderately strong unbleached calico, broad according to the size of the patient, crosses the abdomen on and below the umbilicus. This in the position under consideration I will name "counter-traction band." By means of the cord at each end it is fixed at the proper degree of tension behind (2). A similar strip of calico passes across the back on a level with the point of greatest curve. This is the "traction band" (3). If the projection be very sharp and angular, it is well to make a slit, lengthwise as regards the belt, two or three inches long, so that one of the laps may lie above, the other below the most prominent vertebra; a cord secured to both ends of this forms the whole into a loop, into which is hitched the hook of the system of pulleys. These two strips of calico would always crumple up and run into ropes as soon as tension comes on them unless prevented, which is easily done by having at hand four slips of common soft wood a little longer than the belts are broad. They are to be placed outside the calico pretty close to the patient's body (4), one on each side, and into them through the belts and just at their edges, are thrust surveyor's pins (5). Lastly, a one inch wide loop of webbing, properly padded, passes across the manubrium sterni under the axilla on each side, and is secured by a cord running through a single pulley at proper tension behind (6). This I call simply the "lanyard." Now the surgeon begins by making very slight traction by means of the system of pulleys, observing if the tension of his other cords is correct, and places the spine in proper position; if not, it can easily be altered by means of the single pulleys through which the cords run. All being correct, he increases the tension, and slips between the laps of both traction and counter-traction bands a board of wood, from ten to twelve inches long, in order to prevent lateral pressure on the thorax and abdomen (7). He now increases traction up to the desirable point, recollecting that the Astley Cooper system of pulleys, which is that which I use, multiplies his manual force by six. When as much traction as he may deem safe has been attained, he fixes the pulley cord by twisting or knotting it to the loop of the traction belt, thus causing the spine to be immobile during application of the jacket.

As this sitting position and slight restraint are either not at all or but very little fatiguing to the patient, the next procedures need not be hurried. Moreover, in order to ensure greater hardness and durability to the jacket, some

colloid may advantageously be mixed with the water in which the bandages are soaked. The best and most convenient material I find to be liquid glue (Le Page's). About a teaspoonful to the quart of water causes the plaster to set very firm and hard in from twenty minutes to half an hour, according to the warmth of the room. In winding on the bandages those parts of the traction and counter-traction belts which lie close and tight to the patient's body must be included and covered in the turns; those parts which project and stand away from the trunk are left out. By putting on the bandages not straight but somewhat obliquely, the chest and abdomen may be covered, with the exception of some little triangular spaces lying under the shelter—the eaves, if I may use such a term—of the projecting parts; these are afterwards dealt with.

When the plaster has become firm the traction should be slowly relaxed, and the calico belts cut away about three inches from the trunk, and any little roughness in the angle where they begin to project removed. Then the triangular interspaces should be wetted and covered with plaster soaked in the gluey water. The calico lappets (the three inches not cut away) are then laid over the newly applied plaster and covered by rubbing into them the same material. If the surgeon has to deal with a dorso-lumbar, or with simply a lumbar kyphosis, the lower belt becomes the traction band, passes to the front, and is attached to the pulleys; the upper belt is then the counter-traction band, passing across the front of the chest as high up as one wishes, is secured behind. No lanyard is required.

The advantages of this method over suspension may be thus summed up. 1. Hardly any appreciable fatigue to the patient. 2. No painful pressure on any part. 3. The

Digitized by Google

amount of force employed in straightening the spine, instead of depending on such chance condition as the patient's weight, lies entirely within the surgeon's choice. 4. The surgeon may occupy what time he finds necessary in putting on the bandage, and can make a much more perfected one than when hurried. 5. The admixture of glue renders the jacket very durable and strong, capable of upholding a heavy much-curved trunk. 6. Less plaster is needed, therefore the jacket is lighter. 7. Bits and flakes of plaster do not chip away into the clothing and bed. 8. If a jacket removable by cutting down the middle be desired, a much more springy and less friable one, more easily taken off and put on without cracking, can thus be obtained.

Wimpole-street, W.

ON THE

PRESENCE OF URO-HÆMATO-PORPHYRIN IN THE URINE IN CHOREA AND ARTICULAR RHEUMATISM.

By ARCHD. E. GARROD, M.A., M.D. OXON., F.R.C.P.

DR. MACMUNN[1] has shown that a pigment, closely resembling hæmato-porphyrin, to which he has given the name of "uro-hæmato-porphyrin," is met with in the urine of sufferers from a variety of morbid conditions, and is especially constant and abundant in that of rheumatic patients. This statement has been confirmed by Le Nobel of Leyden, and I have myself found this substance in almost every case of rheumatic fever out of a considerable number in which I have looked for it. I have also found that the pigment present in rheumatic urine usually shows the characteristic five-banded spectrum (described by Dr. MacMunn) in alkaline solution; although I am inclined to think that in some of my cases the substance present was ordinary hæmato-porphyrin. In acid solution the spectrum of uro-hæmato-porphyrin contains two bands and an intermediate shading, which I cannot distinguish from those of acid hæmato-porphyrin in dilute solution, and Dr. McMunn holds that there is also a band like the urobilin band. The amount present in the urine of rheumatic patients is rarely, if ever, sufficient to impart a characteristic colour to the urine, and, although in some cases the characteristic bands are seen on adding a small quantity of mineral acid to the urine, the presence of this substance can, as a rule, only be recognised by precipitating the pigments and making an acidulated alcoholic extract from the precipitate. Even in such extracts the quantity present is often insufficient to yield an alkaline spectrum, and when this is the case the recognition of the pigment rests upon the observation and measurement of the characteristic acid hæmato-porphyrin bands. Some recent observations by Salkowski[2] upon urines containing hæmato-porphyrin render it probable that the administration of sulphonal may cause the excretion of that substance; and it is therefore important to state that the occurrence of uro-hæmato-porphyrin in the urine in acute rheumatism is quite independent of the salicylic treatment; for I have found it in urine passed immediately after admission to hospital by patients who stated that they had as yet had no treatment for their disease, and whose urine gave no salicylate reaction. In the course of a systematic examination of morbid urines for hæmato-porphyrin pigments, I have obtained some results with regard to chorea which I venture to regard as sufficiently interesting to form the subject of a preliminary note. I have examined the urines of twenty patients suffering from chorea, and in fourteen of these have found uro-hæmato-porphyrin, sometimes in quantities such as are but seldom met with. The quantity of the pigment present appears to bear some relation to the severity of the case; but considerable amounts may be found in the urine of patients who have a persistently subnormal temperature. The analysis of the cases shows that the presence of uro-hæmato-porphyrin is most constant in cases in which there is reason to suspect a rheumatic taint. Of the twenty patients referred to, five had definite personal histories of articular rheumatism, and all of these were passing uro-hæmato-porphyrin in their urine—four of them in considerable quantities and one in traces only; two had doubtful histories of articular rheumatism, and both of these had uro-hæmato porphyrin in their urine—one in considerable and the other in unusually large amount; three had murmurs, but nothing else to suggest rheumatism, and of these—two were passing urine containing considerable quantities of uro-hæmato-porphyrin, one with a trace only; two had clear family histories of rheumatism, but no personal histories, and no murmurs—the urine of one of these contained a trace of the pigment, that of the other none. The remaining eight patients had no rheumatic family or personal histories, and no cardiac murmurs. Of these, three had uro-hæmato-porphyrin in their urine: one in unusual amount, one in considerable quantity, and one a trace only. The urine of the other five contained no uro hæmato-porphyrin when examined. Since the presence of the pigment in the urine is by no means peculiar to rheumatic cases, but is only an unusually frequent phenomenon in that disease, the above results, did they stand alone, would scarcely offer any evidence of the part which rheumatism plays in the causation of chorea; but, when they are taken in conjunction with the evidence derived from other sources, they must, I think, be acknowledged to supply a fresh link between these two conditions. This conviction gained in force from the fact that I have not obtained such results in other nervous disorders; but up till now my observations on the urine of patients suffering from such diseases are few in number, and it is quite possible that the results of a further search may tend to invalidate this argument. However this may be, I believe that the frequent occurrence of uro-hæmato-porphyrin in the urine of choreic patients affords evidence that one at least of the perverted chemical processes which accompanies rheumatic attacks is shared by chorea; and that it may be ultimately found that the presence or absence of this pigment affords a means more delicate than any which we yet possess of distinguishing which cases of chorea are due to the rheumatic taint and which own some different causation. In conclusion, I must express my thanks to Drs. Sturges, Barlow, Hadden, and Herringham, who have kindly allowed me to examine the urine from some of their cases of chorea.

ON THE TREATMENT OF

STRICTURE OF THE URETHRA BY HOLT'S METHOD OF DILATATION,

WITH A MODIFICATION OF VOILLEMIER'S DILATOR.

By SURGEON-MAJOR EDWARD LAWRIE.

FOR want of an instrument of precision, Holt's method of dilatation of stricture of the urethra has been to a great extent superseded by internal urethrotomy. This want has, I believe, been remedied by the introduction of a dilator fulfilling all the requirements of such an instrument, which Messrs. Arnold and Sons have made at my suggestion; and Holt's operation will, I trust, now take its proper position as in all probability the soundest and safest method of treating organic stricture. The instrument Messrs. Arnold

and Sons have made consists of a branching dilator constructed on Voillemier's principle. The branches, which are passed through the constriction as a No. 3 Lister's steel bougie, fit into two grooves in the dilator, so

Digitized by Google

that when it is introduced it dilates the stricture to the size and shape of No. 8 or No. 12 It is doubtful what the action of the old dilators generally was on the stricture. Probably they ruptured or split it in one or two directions; but they were faulty in that the branches were liable to separate to a greater extent than the size either of the dilator or of the urethra, and the splitting was consequently not confined in all cases to the stricture. There is no doubt as to the action of my instrument. It is confined to the stricture, which it dilates by multiple splitting or nicking. The first case in which it was employed, for the purpose of demonstration, was one of very tight stricture of the meatus; and after the dilatation the whole edge of the circumference of the stricture was nicked all round as regularly as if it had been done with a very fine knife. The splitting action of the instrument may vary in this respect, but it can have no injurious effect on the sound urethra. In internal urethrotomy, on the other hand, no skill on the part of the surgeon can confine the limits of the incision to the stricture; except by pure accident, the incision must commence and terminate in the sound urethra. The risks of internal urethrotomy as regards hæmorrhage, inflammation, and blood poisoning are therefore appreciably greater than those of Holt's dilatation with the new instrument.

In choosing between internal urethrotomy and Holt's or any other operation in the treatment of stricture of the urethra, surgeons are apt to forget that these procedures do not cure the disease. The cure of organic stricture is accomplished by the repeated passage of full-sized instruments, and the operative procedures merely shorten treatment or hasten recovery. They are beneficial by the precise amount of time they save in enabling the surgeon to pass a full-sized sound with safety. There are risks in internal urethrotomy due to the above-mentioned inherent defect in the operation which are not now encountered in Holt's operation. The only risk attaching to Holt's method is the possibility of urethral fever, which may arise from instrumentation of any kind when the urinary organs are diseased. The danger of urethral fever may be reduced to a minimum, however, by the use of tartar emetic, and a grain- or two-grain dose administered in suitable cases immediately before or after the dilatation of the stricture may be relied upon to control or prevent subsequent inflammatory or febrile disturbance.

It remains to be considered whether Holt's method of dilatation is applicable to the treatment of all strictures of the urethra. My experience is that it is effective in all organic strictures that are permeable by metallic instruments. I have always regarded it as a fortunate circumstance that I was strongly influenced against the use of soft instruments by seeing a false passage made in Paris in the year 1868. One of the most celebrated French surgeons of the day was trying to pass a soft instrument through a stricture, and while he was explaining to the students that it could not possibly do any harm, its point suddenly protruded through the patient's anus. From that day to this I have not attempted to use a soft bougie, and I have never met with an organic stricture through which a metallic instrument could not be passed. The case is different with traumatic stricture. The passage of instruments, which undoubtedly cures organic stricture, has no effect upon the traumatic disease. In traumatic strictures external urethrotomy by Wheelhouse's method is often a necessary operation; but no form of external urethrotomy is necessary in organic stricture unless the surgeon entirely fails to pass a dilator through it. Prolonged experience has convinced me that under no circumstances whatever is external urethrotomy a justifiable operation, and it ought to be banished from the practice of surgery.

Hyderabad.

CURRENT "FROM THE MAIN."—No. II.

By W. S. HEDLEY, M.D.

THE instrument foreshadowed in my recent communication[1] has now appeared. That electric light circuits are easily available for electro-therapeutic purposes may be accepted as an established fact. The time therefore seems to have arrived to carry the inquiry a stage onward, and to ask, With what measure of safety? The danger is the possible influx of strong currents. It is clear that against this risk our ultimate protection at present must lie in the safety fuse or "cut-out." It seems to me also clear that with a really reliable "cut-out" between him and the mains the physician may, by suitable methods, handle electric light circuits without misgiving. But what is a really reliable "cut-out," and where is it to be found? I think it is not to be found in a large proportion of the ordinary fuses used in electric lighting. First, because in light installations a fuse that acts within from 5 to 10 per cent. of the normal current is considered to be safe and satisfactory—e.g., a fuse set to break at 1 ampère would be within a sufficiently close percentage if it acted at 1·1 or 0·9, a margin of possible variation amounting to 0·2 or 100 milliampères in 500. This is not sensitive enough for us. Secondly, in electric lighting it is the practice to insert a fuse whose breaking point is from 50 to 100 per cent. above the normal current. Thus, to protect a 3 ampère circuit a fuse marked to break at 5 would probably be used. This adds another element of uncertainty and danger.

We must have a device that will automatically break a small current circuit with unfailing exactness, or shunt the greater portion of any sudden influx through another circuit. On making known my requirements I have lately been supplied with the former, and I regard it as a most ingenious and reliable instrument. It can always be in full view of the operator, can be set to exact requirements, can be tested at any time, its working parts are of the simplest description, and, set as it is now, it breaks circuit with unerring accuracy at 500 milliampères. It is the invention, I believe, of Mr. Cunynghame,[2] and its description is as follows:—The two ends of a copper solenoid dip into two mercury cups, and on the current reaching the predetermined amount the solenoid is "sucked over" by (i.e., drawn back upon) a fixed iron core. The solenoid is pivoted at the bottom, so that, as soon as it deviates a little *from* the centre, it drops by the force of gravity carrying its ends out of the mercury, and so breaking circuit. A magnetic "cut-out" of this description seems to me to have certain advantages over a fuse, the chief of which is that the exact breaking point can always be ascertained without destroying it. This instrument seems all that could be desired as a circuit breaker. Of course, as already mentioned, it is in the highest degree improbable that it would often be called upon to act. Still the possibility should not exist that a current strong enough to call it into action might pass through the body. To make this impossible the electro-therapeutic circuit ought to be a shunt circuit—i.e., only receiving a certain proportion of the possible maximum—a proportion that can be adjusted according to requirements in a way somewhat similar to that by which we shunt a galvanometer to read 5, 50, or 500 milliampères. Resistances up to, say, 100,000 ohms should be available for this shunt. Suppose the predetermined amount of current that the "cut-out" will allow to pass to be 500 milliampères, in a one-fifth shunt the possible maximum would be 100 milliampères, capable of reduction by the adjustable resistances to any required minimum, which could not be exceeded even were the "cut-out" protected circuit breaking at 500 milliampères. But a break of even the smallest current may be prevented by means of an arrangement that will, instead of *breaking* the main circuit, *shunt* the greater portion of it. Thus, then, we are safeguarded. Our first line of defence is an effective "cut-out" to break the current at a predetermined amount, or to shunt any sudden influx. Our second defence consists in the fact that we are working on a by-circuit, and not on one that allows a current of 500 milliampères through all resistances to pass before it breaks. Our third line of defence lies in the adjustable resistances whereby we can bring down the shunt-reduced maximum to any desired figure, however small. These resistances are absolutely reliable, and afford, in fact, a smoother, safer, and more satisfactory method of regulating current strength than even the cell collector, upon which, in this country at least, many of us are accustomed so implicitly to rely.

RECTAL ANTISEPTIC INJECTIONS IN EPIDEMIC INFLUENZA AND IN ADVANCED PHTHISIS WITH LARGE CAVITIES.

BY J. C. VOIGT, M.D. EDIN.,
FORMERLY RESIDENT MEDICAL OFFICER, BURY AND SOUTHPORT INFIRMARIES.

ON Dec. 23rd, 1891, I was called to a case of advanced phthisis. I found the patient prostrate, with a temperature of 103° F. She had been absolutely confined to bed for twenty-three days. There were profuse night perspirations and tubercular diarrhœa—fifteen loose stools in the previous twenty-four hours. There were the characteristic hectic flush and club-shaped nails. The patient had had no sound, refreshing sleep for more than a week. The cough was incessant. The profuse yellow expectoration showed abundant tubercle bacilli when examined by the Ziehl-Neelsen method of staining. The physical signs indicated a large cavity at the right apex and consolidation over the upper half of the left lung. After first trying to reduce the temperature by hydrochlorate of quinine in combination with antipyrin, and to check the diarrhœa by dilute sulphuric acid with small doses of tincture of opium, I, finding that the patient was losing strength, began on the night of Dec. 24th to give rectal injections of half a drachm of the oil of eucalyptus globulus in a tablespoonful of warm olive oil. Five of these injections were afterwards given every day till the evening of Jan. 2nd, 1892. By that time three ounces of eucalyptus oil had been injected. The patient was then able to sit up and walk about in her room. Her temperature was normal, and had been so since Dec. 27th. The diarrhœa had ceased altogether on the 25th (the second day of the treatment by injections). The night sweats had persisted till Dec. 31st, when they also ceased. The patient now had sound refreshing sleep every night, and ate heartily every day. With the results in this case before me, I was led to try the germicidal action of eucalptus by rectal injections in cases of influenza in the present epidemic. The following are brief notes of four recent cases only, in which these antiseptic injections constituted all the treatment as far as drugs are concerned. They are taken at random from my note-book, and are fairly typical of over fifty other cases treated similarly during the past month.

CASE 1.—T. L——, a girl aged six. Influenza. Patient first seen in the afternoon on Jan. 22nd. Temperature 103°. There was much pain in the frontal region and in the limbs and back. A rectal injection of half a drachm of pure oil of eucalyptus globulus in an ounce of warm olive oil was given at 3 o'clock. This was repeated three hours afterwards. Half an hour after the first injection she fell asleep, and when she awoke asked for milk, and drank some. That evening the temperature was 102°. The injections were continued every three hours. The next morning the temperature was 100°.—Jan. 24th: Three more injections; all pain gone; evening temperature normal.—25th: The temperature remains normal; injections discontinued; child eats well and plays; is quite cheerful; no further treatment necessary.

CASE 2.—Mrs. H——, aged forty-five. First symptoms commenced on Jan. 22nd early in the morning. First seen in evening (8 o'clock); temperature then 102°. Great pain in frontal region and in back. At 8.30 P.M. one drachm of eucalyptus oil with an ounce of warm olive oil was injected into the bowel. This was repeated at 10.30 P.M.—23rd: Morning temperature 101°; pain continues; injection every two hours (dose as before). At night much less pain in head; pain in back almost gone; temperature 99·8°—24th, morning: All pain gone; temperature normal. During the day three more injections. At night temperature normal. Patient got up on the following day.

CASE 3.—Mr. J——, aged fifty-two. Severe influenza began on Jan 21st, with very acute pains; temperature 103°. Rectal injections of eucalyptus every two hours during the day.—22nd: Three more injections; all pain gone; temperature normal in the evening.—23rd: Patient gets up; eats well.—24th: Goes out of doors. Although weather damp and cold, has no relapse.

CASE 4.—Mrs. W——, aged forty. Seen on Jan. 21st. Temperature 102·6°. Three rectal injections (one every two hours).—22nd: Four more injections in the evening. All pain gone; temperature 99°.—23rd: Found her downstairs. Temperature normal; eats heartily.

Remarks.—The antiseptic action of rectal injections of eucalyptus oil is efficacious in cutting short an attack of influenza, and in preventing altogether that nervous prostration and general break down which accompany and follow the disease, provided always that one is called to the case at a sufficiently early stage of the illness, and that there is no contraindication in the state of the heart or kidneys. For adults, without coexisting heart or kidney disease, a drachm of the pure oil of eucalyptus globulus is mixed with nearly an ounce of warm olive oil. An india-rubber ball syringe is filled with this mixture for each injection. The injections are at first given every two hours. When improvement sets in the dose is reduced to half a drachm of the eucalyptus, and the injections are given less frequently.

Southport.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

CHRONIC INTERSTITIAL MASTITIS (TUBERCULAR) WITH CARCINOMA.

BY W. S. CRAWFORD, B.A. CANTAB.,
ASSISTANT SURGEON, LIVERPOOL CANCER AND SKIN HOSPITAL.

THE following case came under my care at the Liverpool Cancer and Skin Hospital, and appears interesting on account of the association of tubercle and carcinoma.

C. S——, aged forty-one years, sixteen years married. She has had six children (nursed by herself) and six miscarriages during this period. In her first lactation she had acute inflammation of both breasts, which subsided without the formation of abscess. Two years and a half ago she noticed some lumps in her right armpit, which were perfectly painless and remained quiescent for some time. Six months later she was confined; she suckled the child for twelve months by both breasts; very little milk was secreted by the right one. At the end of this period of nursing she noticed a hard lump in the outer part of the right breast; the swelling in the axilla had been increasing in size and was painless. Her mother died of consumption; there was no family history of cancer. On examination, in the beginning of November, 1891, the woman was very thin, pale, and miserable-looking. She stated that she had lost much flesh recently. The right breast was thin and atrophied, more so than the left; at the upper and outer border a small lump could be seen, about the size of a filbert; the skin over this area was puckered, presenting the well-known "pig-skin" appearance. This swelling was found to be intimately incorporated with breast tissue, somewhat irregular in outline, and firmly attached to the skin; the remainder of the breast was tough to the feel, adherent to the deeper structures, and riddled throughout with small shot-like bodies. Two lymphatic glands under the free margin of the pectoralis major were found enlarged and very hard. Filling up the top of the axilla was a fluctuating painless swelling, mixed up with an indefinite hard mass. Operation: Removal of breast and glands. Some difficulty was experienced in removing the breast from the underlying structures on account of the intimate adhesion and thickness of the fibrous tissue. On making an incision into the axilla about two ounces of thick curdy pus escaped, and a mass of caseating glands was removed. The wound was healed in a fortnight. On Jan 30th, 1892, the woman presented herself for examination. She had put on flesh, and had lost her woe-begone expression. The operation incisions were sound, and there was no recurrence. Examination of parts removed: The breast consisted of tough fibrous tissue, interspersed throughout with small cysts; the majority of these when opened contained caseous material, some few containing puriform fluid. The lump at the outer corner of the breast cut like typical scirrhus; the two isolated lymphatic glands were very hard and grated on section. The axillary mass consisted of the partial outlines of six or eight glands caseating throughout.

The tumour was microscopically examined by my friend,

Digitized by Google

Mr. Thelwall Thomas, and the sections exhibited at the Liverpool Medical Institution, on Jan. 28th of the present year. The following is his report:—The breast shows a large amount of interstitial fibrous tissue, some of it in process of formation, distended gland spaces containing a central mass of caseous material without definite structure, surrounded by a few irregular rows of apparently proliferating acinous cells, the majority irregularly cubical in shape, others appearing more or less flattened. This description applies to every gland space examined with the exception of a few, in which only a small number of the cells remained, along with small fragments of the caseous material. The nodule at the outer corner is typical scirrhus, as well-marked a specimen as can be met with no cysts in this mass. The lymphatic glands on the way to the axilla contain numerous well-marked giant cells with nuclei at their periphery, placed in the centre of an irregular mass of small round cells, evidently nodules of tubercle, immediately adjoining which are found a well-marked alveolar stroma, containing small cubical cells of secondary carcinoma (from the breast). The caseous glands in the apex of the axilla are tubercular: many giant cells are found, and in a few sections are distinctly seen cells somewhat cutical in outline, with an indefinite alveolar stroma—most probably early nodules of secondary carcinoma.

Remarks.—In a large number of specimens from several cases of simple chronic interstitial mastitis (some of which had a carcinomatous nodule in them) we have been unable to find any marked caseating changes in the gland acini, which leads us to look on this one as probably tubercular, notwithstanding the absence of giant cells and bacilli of tubercle, which have been carefully sought for. The lymphatic glands have certainly tubercle and carcinoma intermixed.

Liverpool.

CASE OF CHOREA TREATED BY CHLORAL HYDRATE.

By B. BASKETT, M.R.C.S., L.R.C.P.

THE following is a case which recently occurred in the Bristol General Hospital, where I was physicians' assistant at that time, and which, as it may be of interest, I am allowed to publish by the kind permission of Dr. J. Mitchell Clarke.

A. Y——, a strong, well-nourished girl of fourteen years of age, engaged as a pupil teacher in a national school, was admitted on Aug. 24th for rheumatism accompanied with chorea. It was her first attack, was mainly right sided, and presented no unusual feature; it was attributed to excessive mental work. She improved with rest and treatment—viz., first salicylate of soda, and subsequently Fowler's solution—up till Sept. 3rd, when, under the agitation caused by the conduct of a patient in a neighbouring bed, she fell into a state of furious excitement. Her movements became incessant and maniacal in character, so violent that she was constantly being thrown out of bed, and had to be tied down with boards let in at the sides. She seemed conscious all the while, and to understand what was said; she obviously, for instance, tried to answer questions, but could not frame the words. She was at once isolated, and at night chloral, at first combined with bromide of potassium, was given in fifteen doses of each, the arsenic being continued during the day. On the night of Sept. 4th I gave her thirty grains of each without producing any sleep, and increased it to forty on the night of the 5th with equally little effect. On Sept. 6th, as she was becoming completely worn out, and had had no sleep since Sept. 3rd, while it was obvious that if the movements were not in some way checked she must, sooner or later, die, I administered chloroform. She was kept under for several hours, but when she came round was as bad as ever. It was then determined to make a systematic attempt to chloralise her, and for the next four days doses were administered at frequent intervals according to the results produced. It was given not so much with the intention of producing sleep as with that of checking the movements. She was, of course, under careful observation, special attention being paid to the temperature and the state of the pulse. The quantity given at each dose, and the intervals between the doses, were left to the judgment of the resident officer in charge at any given time; for instance, she was never roused from sleep except to be fed, and if one dose was ineffectual, another was given within the hour. Acting on this method, within a few hours from the time that chloralisation was begun on the night of Sept. 6th, she was got under the influence of the drug and kept more or less so for the next four days, the quantity required to produce the effect being altogether about a hundred grains daily. She was fed by the mouth when possible, but enemata of milk, eggs, and brandy were frequently administered also. During the height of the attack her temperature rose to about 103°, and kept at that level with slight fluctuations. This was probably due to the waking up of the rheumatism she had suffered from in the beginning, because she exhibited signs of pain and tenderness in the ankles, though there was no swelling there, and because at this time, and not till then, a very loud systolic murmur was to be heard at the apex, which could be heard up to the date of her discharge. It is worthy of remark that the chloral had no perceptible effect on the temperature. By Sept. 11th the violent movements had entirely disappeared, and she would sleep for hours after the administration of one dose of ten grains. She had gained ground so far that the choreic movements were decidedly less marked than they were just before this acute exacerbation. The probability, indeed, is that if the chloral had been further pushed a few days more she would have been entirely cured of chorea. But, reduced as she was, in the absence of urgent symptoms, and bearing in mind the cardiac mischief, it was considered better to reduce the quantity of the drug and substitute tonic treatment as soon as possible. From the result of this case it seems probable that we could—at the expenditure, it is true, of considerable trouble—reduce very materially the length of time spent in the cure (or watching rather, for it is surely doubtful whether the patient recovers any the sooner for the exhibition of the drugs ordinarily used) of cases of chorea. Unfortunately I have had only once the chance of seeing it used in any other case—viz, that of a man of twenty-four. It was a rather severe case, but the chloral was not pushed. However, with fifteen-grain doses every four hours, he was certainly and considerably benefited, but he insisted on leaving hospital in a few days' time before any marked result could reasonably be expected.

Cotham, Bristol.

CASE OF PUERPERAL ECLAMPSIA; RECOVERY.

By WILLIAM ROBERTS, M.R.C.S. & L.R.C.P.LOND.,
AND
CHESMAN BARKER, M.R.C.S. & L.R.C.P.

THE following case may be worthy of record in THE LANCET:—

Mrs. H——, aged twenty-two, is a primipara, and had arrived at the thirty-eighth week of her pregnancy without any untoward symptom, when on the afternoon of March 14th, 1892, she was seized with nausea and vomiting, and at 7 P.M. with an epileptiform convulsion, which, although bilateral, was stronger and more violent on the right side; she then rapidly became unconscious. There was then slight œdema of the legs and feet and puffiness of the face, and the urine was scanty and turbid, and contained about half of albumen. The skin was dry and harsh, the temperature 101°, and the radial pulse 120, and the arterial tension decidedly raised. The breathing was frequent and stertorous. Chloral (20 grs.) and bromide of potassium (30 grs.) were prescribed every four hours, but seven more fits occurred at intervals of half an hour, the patient still remaining comatose. Feeling certain that unless something were done the patient would speedily die, we decided to empty the uterus, and at 9 P.M. passed a gum-elastic catheter between the membranes and the uterine wall for a length of six inches. We also administered two minims of croton oil, which soon produced several copious evacuations. At 3 A.M. on the 15th the patient began to show signs of irritation, so chloroform was administered, and at 4 A.M., the os being completely dilated, the catheter was removed, the membranes were ruptured, and the woman was delivered by the aid of the forceps of a living female child in about ten minutes from rupturing the membranes. The placenta came away without trouble, and there was but little hæmorrhage. The administration of chloroform was then discontinued, and the patient left, as she appeared to be no worse. At 12 A.M. we found her still comatose, and

Digitized by Google

were told that she had had four more convulsions. The skin being still very dry, and very little urine having been passed, and that into the bed, we gave her a hypodermic injection of a quarter of a grain of pilocarpine at 1 45 P.M. At 7 P.M. she was still unconscious, but was perspiring profusely, and had also retained some milk and soda-water, all previous attempts at feeding having been unsuccessful. On the morning of the 16th, forty-eight hours after the commencement of the coma, she became conscious, and then complained of severe headache and complete amaurosis. She was then put on twenty-grain doses of citrate of potash every four hours. In the course of the day she passed urine, which on examination contained one-sixth of albumen, which has since almost disappeared. She then made an uninterrupted recovery, regaining her sight in twenty-four hours, and at the present is up and attending to her household duties, and is suckling the infant, which is also quite well.

The interest attaching to the case lies in the success which attended the treatment, as regards both the child and the mother. Knowing, as everyone does, the almost uninterrupted fatality of cases occurring before labour, it is with the greatest pleasure that we put on record a case in which not only the mother completely recovered, but the child also survived. We wish to add our testimony to the advisability of immediate operative treatment in all cases occurring late in pregnancy, the nature of the procedure of course depending on the severity of the case. Inasmuch as in our case the convulsions themselves were not very frequent, we decided to bring on labour gradually; but, in a case in which the convulsions threatened to terminate life by their frequency and severity, we should not hesitate to empty the uterus by dilatation with Hegar's dilators.

Cambridge-gardens, W.

A CASE OF ENTERIC FEVER,

IN WHICH SYMPTOMS OF PYÆMIA APPEARED ON THE THIRTIETH AND DEATH OCCURRED ON THE THIRTY-SEVENTH DAY OF ILLNESS.

By IAIN CLERK, M.B.,

PHYSICIAN-SUPERINTENDENT TO THE JOINT BURGHS FEVER HOSPITAL, KNIGHTSWOOD, GLASGOW.

THE formation of small abscesses in certain parts of the body is not unusual in enteric fever, especially if the case has been a long-drawn-out one, or when rapid emaciation has taken place. With regard to abscesses, Murchison has the following note: "I have met with many instances in which, during convalescence, abscesses have formed beneath the skin in different parts of the body. ..... In rarer instances pus is deposited in the joints or in some of the internal organs, and then the case usually terminates fatally." The following short account of a case in which symptoms of pyæmia appeared on the thirtieth and death occurred on the thirty-seventh day of illness is, I think, worthy of record, seeing such a complication is somewhat unusual in this disease.

J. K——, aged twenty-eight, labourer, was admitted to the Joint Burghs Hospital on Sept. 30th, 1891, certified as suffering from enteric fever. His illness began eight days before admission, with headache, shivering, vomiting, general weakness, &c. It is not necessary to follow the history of the case, as there was nothing special to note, with the exception, perhaps, that the crop of rose papules was very profuse over the abdomen and chest. The highest temperature recorded was 103·8° F. There was no looseness of the bowels, although from colour and odour the stools were characteristic enough. The temperature, which all through his illness was very steady, became variable after the twenty-sixth,[1] dropping on the twenty-ninth to 98° in the morning, but rising in the evening to 103°. Thirtieth day: Morning temperature 103°, evening 101·8°. Thirty-first: Morning temperature 102°, evening 104°; and after this it ranged between 102° and 104°, or sometimes slightly over.

On the thirtieth day of illness the right cheek was seen to bulge a little, and on the following day the right eye was completely closed, the upper and lower eyelids being largely swollen. On the thirty-third day the left eye became involved, both lids swollen enormously, and the eye closed. On the thirty-fifth day a large swelling, not glandular, appeared in both sides of the neck at the angles of the jaws, and by this time the outer half of the right upper eyelid sloughed away, and there was considerable bogginess in the right temporal fossa and over the right ear. In all of those places named collections of pus took place with alarming rapidity; and although openings and counter-openings were made freely and early, sloughings of portions of both upper eyelids took place, and the patient gradually sank, and died on the thirty-seventh day of illness. As the temperature did not drop at the end of three weeks, it is likely that inflammatory action was still going on in the lower part of the small bowel; and it is conceivable that some purulent matter from an ulcerating patch may have got into the circulation, and, possibly carrying the enteric poison with it, given rise to those abscesses of which I have spoken. From the absence of glandular enlargement, it seems to have passed by the blood circulatory rather than the lymphatic system.

Glasgow.

[1] I mean *day of illness*, not day of the month, so much in vogue, but practically valueless.

A CASE OF HYOSCINE POISONING TREATED BY PILOCARPINE.

By HERBERT L. EVANS, M.B., C.M. EDIN.

IN connexion with the case of poisoning by hyoscine and that of poisoning by pilocarpine mentioned on pages 328 and 329 respectively of THE LANCET of Feb. 6th, 1892, the following may be of interest:—

On Oct. 16th, 1890, I was called to J. B——, a case of delirium tremens, at 4.45 A.M. He had just had a fit. This, in his case, was no unusual occurrence, his first attack having begun on Sept. 20th of the same year with an epileptiform seizure. Chloral, bromides, and morphia had previously failed to produce sleep, so a two-minim injection of a 1 per cent. solution of hyoscine was given, but this also failed. Eight hours later he had nearly three minims by the mouth, with no better result. In the evening morphia and chloral were given without effect. Later on, as he could not be kept in bed and was quite unmanageable, a three-minim injection of hyoscine of presumably the same strength, but from a different bottle, was given. The patient rapidly became comatose with dilated pupils and arteries, rapid pulse, congested face, hot, dry skin, and rapid and deep breathing. Morphia was injected, but without any apparent improvement. Directing that the patient should be energetically stimulated by pinching, I hurried to the surgery, and on returning with pilocarpine found that, as before, the patient could not be roused. Unfortunately no record of the injections of this was kept. So urgent seemed the necessity of producing symptoms approaching those characteristic of the drug that injections were made in the thighs and arms at intervals of about five minutes. In a short time there was a faint reaction of the pupils to light, with a tendency to moistness of skin, whilst the breathing and pulse improved; and on my next holding the candle to the face I was gratified by seeing the patient knock it from my hand, after which rapid improvement took place, followed by complete recovery. Great soreness and itching were complained of next day, the latter relieved by alkaline washes and cocaine ointment. His thighs and arms showed marks of about eight punctures, and he had probably had about two grains of nitrate of pilocarpine. His general health improved under strychnine, red extract of cinchona, &c., so that in a short time he was able to indulge in shooting and billiards, and seemed to have no craving for liquor.

Goring-on-Thames.

HOSPITAL FOR SICK CHILDREN AND WOMEN, BRISTOL.—The year 1891 completed the twenty-fifth year of this institution, and the annual report just issued records some interesting details on the history and career of the charity covering that period. In 1866 the hospital opened with six cots. The beds now number 100. The medical statistics of the past year show that more patients were treated both in the hospital and as out-door patients than in any former twelve months. The average annual expenditure is estimated now at £3300. The year's income from all sources (except legacies) fell short of the expenditure by £151 6*s.* 10*d.* The deficit had, however, been discharged out of a legacy received of £2964 14*s.* 7*d.*; the current year consequently began freed of an adverse balance.

ROYAL FREE HOSPITAL.

CASE OF IMPACTION OF THE GILL-PLATE OF A HERRING IN THE LARYNX OF AN INFANT; TRACHEOTOMY; REMOVAL OF BONE; DIFFICULTY IN REMOVAL OF TUBE FROM FUNCTIONAL PARALYSIS OF ABDUCTORS; COMPLETE RECOVERY.

(Under the care of Dr. SAMUEL WEST.)

THIS case is interesting in two particulars: first, on account of the period of latency; and, secondly, because of the difficulty in the subsequent removal of the tube. The impaction of the bone in the larynx was marked by an initial attack of dyspnœa of great severity. The dyspnœa quickly subsided, and for four days continued so slight that no serious importance was attached to it. At the end of that time, however, it returned, and rapidly became urgent. The explanation is clear. The initial attack was due to the spasm set up, and the subsequent dyspnœa to the consecutive inflammation. The first was transitory and the second permanent. The difficulty in removing the tube was without doubt due to the closure of the glottis as the result of paralysis of the abductors, for the child could cry audibly though it could not inspire. The abductor paralysis was, Dr. West thought, the result of disuse, of laziness if we like to call it so, of the abductor muscles, and it was not until they had been roused to action again by the means used to dilate the glottis that they began to functionate.

Kate C——, a healthy infant aged nine months, was brought into the hospital suffering from considerable dyspnœa, with stridor and great recession of the chest walls. The movements of the larynx on respiration were greatly exaggerated. The face was pale and the child drowsy. The diagnosis was made of obstruction to the main air tube, in all probability in the larynx, and the history favoured the view that it was due to a laryngitis excited by a foreign body. The condition of the child was so serious that tracheotomy was performed at once, with immediate relief to the symptoms, after which the child went to sleep and slept comfortably the whole night. The mother stated that the child was perfectly well until the middle of the day on July 30th, 1889. It was then quite suddenly seized with urgent dyspnœa, and was thought to have swallowed a plum-stone. After a little while the urgency of the dyspnœa passed off, and, though the breathing continued short during the rest of that day and the next day, it was not bad enough to call in a doctor, and on the afternoon of the 31st the child was brought to the out-patient room, but, in spite of the history, was not thought to be a case for admission. The next day it was still better, and played about cheerfully all day; but at 10 o'clock in the evening the dyspnœa returned, and rapidly became worse, so that early on the morning of Aug. 2nd the child was brought to the hospital and admitted. When Dr. West saw it in the afternoon he advised instant tracheotomy. On the evening of the 2nd after the operation the temperature rose to 101·2°, and the next morning to 101·4°, and then fell gradually to below normal on the 5th, rising, however, the next day to 100·4°, but from this time it remained, with one or two exceptions, due to accidental causes, steadily below normal. The child progressed favourably till the morning of the 6th, when a severe attack of dyspnœa set in again suddenly. This lasted but a short time, and did not recur until midday, but lasted until Dr. West saw it about 3 o'clock. There was then considerable recession, and the child was cyanosed. The tube was removed, and after a violent fit of coughing a piece of the antiseptic gauze with which the wound had been dressed was coughed up. The dyspnœa still continuing, though not so severely, the air tubes were examined with a fine probe as far as could be done; and feeling something hard in the larynx above the wound, Dr. West introduced a pair of forceps, and removed a fishbone. The trachea was next examined and a curved wire passed down it in case there might be any more of the gauze within reach, but none was detected. The removal of the bone did not at once greatly relieve the dyspnœa, but by the next morning the breathing was comparatively easy. In the evening of the 7th the tube was removed, and remained out for about an hour, but the respiration was carried on entirely through the wound. The tube was now left out every day for a short time, and frequently when the tube was out the child cried vigorously. Still it was evident that the air did not pass through the larynx, for after an hour or so, as soon as the granulations round the wound had had time to swell up and close the orifice, dyspnœa set in and the tube had to be replaced. On Aug. 19th it was found that the child was able to breathe for a little time through the larynx, but after this day it became more and more difficult to keep the tube out on account of the dyspnœa produced. On Sept. 5th the child was anæsthetised and a fresh examination made by Mr. Stabb. The tube was removed, and a graduated bougie (No. 11) was passed up through the larynx between the cords. It was then also passed from the mouth downwards through the larynx. The wound was then closed, but dyspnœa immediately returned. A dilator was then taken and passed between the cords, and the blades slightly separated. For a few seconds after this the patient was able to breathe through the mouth when the wound was closed, but dyspnœa again returned, and a silver tube was inserted in the wound. Nothing was felt which could explain the dyspnœa. On the 7th, when the tube was taken out, the breathing through the mouth was perfectly natural and continued so henceforth, so that the tube was not again inserted. The child continued well, and was discharged with the wound completely healed on the 18th. The bone which was removed was one of the gill-plates of a small fish, probably a herring.

MANCHESTER ROYAL INFIRMARY

MYXŒDEMA TREATED BY THYROID GRAFTING.

(Under the care of Dr. THOMAS HARRIS and Mr. G. A. WRIGHT.)

IT is very advisable that this method of treating what has hitherto been an incurable disease should receive the fullest investigation, and cases in which it has been tried be reported. The grafts have been taken from other patients who were suffering from parenchymatous enlargement of the thyroid gland, which was producing symptoms for which it was considered advisable to remove part of the gland, also from sheep and from monkeys. Evidence of the good produced by this grafting when the grafts have retained their vitality and become vascularised is accumulating; but it is necessary to watch the patient for some time before satisfactory conclusions can be come to with regard to the benefit derived by any particular case. We have not space to consider the history of this method of treating myxœdema and allied conditions; the experiments and observations of Schiff, von Eisselsberg, Carle, and others are, however, not only interesting in themselves, but important in that they show the good effect on some of the lower animals, whilst the investigations of other observers prove that the good result of the grafting may be long continued if not permanent.

Mrs. T——, aged forty-eight, was admitted to the Royal Infirmary on March 6th, 1891. There was no family history of goitre or of myxœdema. The patient was a resident in Manchester, though she had travelled a good deal about the country. She was the mother of five children, three of whom are alive and well, two others died from convulsions during teething, and she had had two miscarriages. She gave the following history of her illness. She has been ailing more or less for nine years, when she suffered from a bad attack of bronchitis, and at this time she noticed that her neck was enlarged. The swelling was painted with iodine, but for a time increased until her neck became nearly twice as large as at the time of her admission; it attained its greatest size about eight years ago. She herself attributed the swelling to her persistent cough. The fulness of the neck then began gradually to subside, and she noticed that the ankles and abdomen occasionally swelled; frequency of micturition at night was also a new symptom. About two years and a half ago a still more severe attack of bronchitis came on, and the swelling of the feet and abdomen increased, and finally spread to her face. At this time the neck was nearly natural in size. It is within

swelled; frequency of micturition at night
tion. About two years and a half
of bronchitis came on, and finally
the last two years and a half that the features of the present disease have developed, the most striking symptoms being a slowness of speech, swelling of the face, and weakness, together with a feeling of "strangeness" in the head, and a sensation of the mouth being smaller than natural. Such was the account obtained by the dresser on her admission. Mr. Deakin, surgical registrar, gives the following description of her condition at that time: "She is a fairly well nourished woman of forty-eight. The skin is dry and thick, but (with the exceptions to be presently mentioned) not hard or scurfy; it is in most cases of a yellowish earthy colour, but over the nose and to a certain extent over the cheeks it is dull reddish. The alæ of the nose and the lips are red, smooth, and full, and no wrinkles are to be seen in any part of them. The eyebrows are very much elevated and perfectly uniformly so, and the forehead is marked with three or four lines, horizontal in the centre, and curving over towards the sides. These lines help much to give her the peculiar staring look she possesses. The conjunctivæ are œdematous and glistening. The hair is fairly thick and strong. The mouth, gums, and palate are all rather œdematous. The tongue is markedly enlarged, somewhat pale, and its borders are indented. The eyelids are very markedly swollen and are pale and translucent, especially the lower, which show a distinct, soft, smooth pouch; the whole appearance resembles very closely that seen in chronic Bright's disease. The neck is flabby and soft, and examination of it gives the idea that some tough, hard, shrunken remains of the thyroid can be felt. The skin of the hands is dry, hard, thin, and scaly; the fingers are pointed; the nails are normal, but are overlapped by the skin, so that no groove can be made out. The hands are not unusually large. The abdomen is prominent around the umbilicus; there is no ascites; there is no œdema of the legs; the left limb is longer than the right; there is tenderness of both calves on pressure; the skin of the feet is horny and dry, and the toes are flattened together. The patient is fairly intelligent. Her sight has slowly been failing; her hearing is good; taste perhaps less distinct than it used to be. Pupils normal. Plantar, epigastric, and abdominal reflexes not obtainable; knee-jerk and deep reflexes over radius and olecranon are diminished. Sensation generally seems delayed; her speech is very markedly modified; and mastication and swallowing are slow. Pulse 60; heart normal. Appetite good; bowels regular. Respiration 17, a few râles occasionally. Urine 1010, acid, no sugar, contains a trace of albumen. The red blood-corpuscles were estimated at 5,970,000 per centimetre. No excess of white corpuscles. Hæmoglobin nearly normal in amount."

The patient was kept in hospital, and chiefly in bed, for a month before operation. During that time her general condition improved considerably, and the swelling of the face was less marked; the speech and other conditions remained little altered. On April 4th a curved incision was made below each breast, and the glands were raised a little from the pectoral muscles. Half the thyroid gland of a small, young, green monkey, which was chloroformed to death in the ante-room of the theatre, was then placed under each breast. The wounds were closed and dressed. The operation wounds healed by primary union and without any disturbance, and the patient expressed herself as feeling better. On the 29th she was sent to the convalescent hospital, and her condition then was decidedly better than on admission. The improvement was maintained, and she was sent home after being in the country for some weeks. She relapsed very much into her former state under the less favourable surroundings of her home, and was readmitted to the infirmary very much as she was at first. She again immediately improved, but it is clear that the improvement is due far more to the wholesome circumstances of her hospital life than to any special treatment. Her speech is quite unaltered. She herself, however, is strongly of opinion that she is much improved.

Remarks by Dr. HARRIS and Mr. WRIGHT.—There is, we think, no doubt that this case is clearly one of myxœdema. The history of the affection of the thyroid causing first enlargement and subsequently complete or almost complete atrophy is interesting. The monkey's thyroid was exceedingly small, and though it set up no irritation in its new position, we were quite unable to say whether it remained as it was, was absorbed, or grew. At any rate, we could feel no trace of it afterwards. We fear the temporary improvement must be put down entirely to better hygienic conditions, and so far as the thyroid grafting goes, no conclusion can be drawn from this case.

ROTUNDA LYING-IN HOSPITAL, DUBLIN.

MATERNITY CASES.

(Under the care of Dr. JOHN H. GLENN, Assistant Master.

THE accounts of these cases will be read with interest, as they give descriptions of unusual conditions. The complication of parturition referred to in the first case is luckily a very unusual one, and is not infrequently fatal. Two cases which somewhat resemble it have been recently described: one by Hirschfeld, in which the rupture extended through the cervical part of the uterus, and in which treatment similar to that followed by Dr. Glenn proved successful; another by Dr. Taylor, in which the rent extended through the posterior vaginal wall and was of large size, and which ended fatally in spite of antiseptic precautions. The necropsy does not afford any reason for regarding the hyperpyrexia as due to septic absorption.

CASE 1. *Accidental hæmorrhage; rupture through posterior vaginal vault; recovery.*—M. B——, aged twenty-five, multipara, was admitted to the Rotunda Hospital in labour on the evening of Nov. 18th, 1891. Dr. Glenn was called to the case just after midnight on account of some slight antepartum hæmorrhage. On palpation the child was made out lying in the first vertex position, the uterus was very tense, the lower segment greatly thinned, and the contraction being strongly marked. No fœtal heart could be heard. The bladder was empty. The tenseness of the abdominal walls, the almost constant pain and the general condition all pointed to accidental hæmorrhage. On examination per vaginam the diagnosis was verified by a gush of blood following the pushing up of the head. Having disinfected the external parts, and douched the vagina with carbolic solution (1 in 40), internal version was performed, a foot brought down, and the case left to nature. Half an hour later, the hæmorrhage recurring, traction was made on the foot, and the delivery gradually completed. After the expulsion of the child, hæmorrhage continuing, and the patient looking very collapsed, an ineffectual attempt was made to express the placenta, which, however, was found to have left the uterus. It was removed from the vagina by hand, and at the same time a laceration of the cervix, extending backwards through the posterior vaginal vault, was made out, the arm passing upwards through the rent into the abdominal cavity as far as the elbow. A long strip of iodoform gauze was introduced through the rent, the lower end left in the vagina, a compress and binder applied, and restorative treatment employed. During the afternoon the patient was given a quarter of a grain of morphia hypodermically. The catheter was passed regularly. On the 23rd the plug was removed; no hæmorrhage followed. On the 27th the patient was deeply jaundiced. Her urine was examined for urobilin, but with a negative result. The yellow tinge gradually disappeared, and she made an uninterrupted recovery, the highest temperature being 99·8°. The patient was discharged from hospital on Dec. 18th, 1891.

CASE 2. *Puerperal mania; hyperpyrexia; death*—M. D——, aged twenty, unmarried, primipara, was admitted on Nov. 18th, 1891. Her state of health on admission was good, but she was suffering from considerable mental depression. On Nov. 20th, at midnight, the patient was delivered by forceps, as the temperature had risen to 101·2°. The os was almost fully dilated. No special difficulty was experienced, but the perineum was lacerated, requiring three stitches. The child was born alive. The following day the patient was very unruly, and got out of bed and took her binder off. Her evening temperature on the 23rd was 100·6°; the lochia normal. Nothing of special interest occurred till the 26th, when she was very restless, her face flushed, and with an expression of suspicion. Stitches were removed; the union was perfect. Her evening temperature was 98·6°. On the 27th she developed well-marked mania. Hyoscine ($\frac{1}{75}$ gr.) was given. Evening temperature 102°; pulse 103. Slept badly. The following day the patient was very violent. Bromide of potassium (30 gr.) was administered. Her skin was harsh and dry; wet pack given. Morning temperature 102°, evening 102·4°. On the 29th, at 6 A.M., she had a rigor, and half an hour later her temperature in the axilla was 109·4°. The temperature was verified by three certificated thermometers. Death took place at 7 A.M. Post-mortem examination by Dr. Earl revealed no cause for death; there was no meningitis, and the thoracic and abdominal organs were healthy.

PATHOLOGICAL SOCIETY OF LONDON.

Congenital Dislocations of Radius.—Congenital Malformations of Kittens.—Anencephalous Monster.—Ileo-colic Intussusception from Inverted Meckel's Diverticulum.—Acute Double Tubercular Disease of Testes.—Unusual Distribution of Secondary Cancer.—Ancurysm of Aorta in a Child.—Cystic Adenoma of Kidney.

AN ordinary meeting of this Society was held on April 5th, the President, Sir George Humphry, in the chair.

Mr. F. C. ABBOTT read a paper on nine cases of Congenital Dislocation of Radius, seven of which occurred in one family, the cases having been scattered over four generations. Five of the cases, belonging to three generations, had been examined personally by him, and all presented dislocation of radius forwards in one or both arms. Flexion and extension in all were free, but there was no movement of pronation or supination. In all the cases the deformity had caused the patient a good deal of inconvenience; but no member of the family was the subject of any other deformity. Dissections of the elbows of the youngest of these cases were shown, the chief abnormality being a large protuberance from the outer side of the coronoid process, fixed to the neck of the radius, and possessing an extra centre of ossification. The dissected elbows of a child aged two months were also shown. On the right side there was dislocation of both bones directly backwards, the articular end of the humerus being deeply cleft and much altered in shape. On the left side the radius was dislocated backwards, upwards, and inwards, still keeping its normal relation to the ulna, which articulated with a mass of cartilage attached to the lower part of the shaft of the humerus, representing the trochlea and internal condyle, the lower end of the humerus consisting only of external condyle and capitellum. In this case, the prime cause was evidently in the humerus. A living specimen of congenital dislocation of left radius backwards and outwards in a girl aged twenty-one was also shown.—The PRESIDENT said that in all cases the displacement was slight, and all seemed to be due to want of proper condition of the orbicular ligament. There was a similar case in the Cambridge Museum, in which both humerus and radius were deformed, the neck of the latter being longer than it should be, causing difficulty in flexing the forearm.

Mr. J. JACKSON CLARKE showed a Litter of Five Kittens with various congenital malformations. Their dam had a large abdominal tumour. They were all undersized, all had double hare-lip and cleft palate; one had exophthalmos, four had small and deformed upper extremities, some with suppression of digits. All of them had talipes equino-varus, which in two of the kittens was complicated by complete absence of the tibiæ. There were other deformities. Mr. Clarke attributed all the malformations to the mechanical effects of the abdominal tumour in the dam. Mr. Clarke also showed an anencephalous fœtus with double genu recurvatum, talipes, and proptosis of one eye.—Mr. PARKER regarded the specimens as valuable additions to the pathology of club-foot and similar deformities. The presence of a tumour in the mother was interesting, for he was convinced that it was to the environment that we must look for an explanation of these cases. A mechanical was much more rational than a neurotic origin, fo the children in other respects were usually absolutely normal, and if treated early they recovered completely. They thus differed entirely from nerve lesions, such as talipes from infantile paralysis, in which other evidences of neurotic origin coexisted, such as paralysis, changes in the skin, &c.

Mr. JAMES ADAMS of Eastbourne showed a specimen of Ileo colic Intussusception caused by an inverted Meckel's diverticulum. The patient, a labourer aged forty-two, hitherto in good health, was attacked with symptoms of intestinal obstruction, but under treatment he recovered, and in a week was able to resume work. In three weeks the symptoms returned, but were not relieved by treatment; the vomiting was only slight, and during the last week of his illness ceased altogether. A small quantity of blood was passed on one occasion after an enema, and there was only an occasional slight rise of temperature. There was some fulness, with dulness in the right iliac region, but no tumour could be made out. Peritonitis supervened, and he died three weeks after the beginning of the second attack. At the necropsy an ileo-colic intussusception was found; the ileum, where it passed with the mesentery through the ileo-cæcal valve, was constricted, black in colour, and evidently on the point of becoming gangrenous. The intussusception had sloughed at its distal extremity, and the two layers, with the mesentery, were all firmly bound together by inflammatory adhesions. In the last inch of the entering layer was found an inverted Meckel's diverticulum; it was seated eight inches from the ileo-cæcal valve, was three inches in length, and was covered with mucous membrane. In its interior, which in its inverted condition was formed of its peritoneal coat, was found a piece of fatty mesentery, which had become adherent through inflammation. He had found two other cases of diverticulum associated with intussusception, one in Guy's and one in St. Bartholomew's Museum, and they also occurred in adult males. He suggested that the process commenced by a dimpling of the free end of the diverticulum, which increased, forming an intussusception of that tube, which finally became completely inverted and hung loose in the lumen of the ileum and then acted like a polypus in producing intussusception.—Dr. PYE SMITH asked if Meckel's diverticula had been met with in the female subject. He had never seen one, and the point was worth bearing in mind in the differential diagnosis of cases of intestinal obstruction.

Mr. BARLING showed a specimen of Double Acute Tubercular Disease of the Testicle. The body of each organ was affected, not the epididymis, and in each there was a considerable caseous area, multiple patches existing on the left side. In addition to the caseous districts, there was a marked fibrosis of the adjacent parts of the testicles. Tubercle bacilli were found in preparations made from a caseous area, but there were no well-defined giant cell systems; in fact, the condition was one of infiltration with granulation and epithelioid cells, with catarrh of the seminal tubules, followed by caseative necrosis. The organs were removed from a patient aged thirty-one, who attributed his disease to severe exertion at his work; this was followed by swelling of the testicles four or five hours afterwards. When seen five weeks later the testicles were both swollen, the left especially, painful and tender, the scrotum was slightly œdematous, and there was a little fluid in each tunica vaginalis. The swelling appeared to involve the body and the epididymis, and the cord on each side was thickened. The temperature was of the hectic type, ranging from 103° in the evening to normal or subnormal in the morning. The parts about the base of the bladder were healthy, but there was a suspicion of phthisis. The patient discharged himself from hospital, but was readmitted later. The local condition was then less acute, and the temperature at night was only 100°, remitting to 98° in the morning. Castration was performed nineteen weeks after the injury, the temperature at once becoming normal, and the patient's general condition improved markedly afterwards. Mr. Barling believed the condition was a very rare one.—Mr. J. J. CLARKE had recently examined a similar case under the care of Mr. Page. The patient was a publican and an athlete, and the testes became rapidly involved one after the other. One which was removed showed undoubted tubercular lesion. Another instance of bilateral disease coming on extremely rapidly he had met with in a medical student.

Dr. PYE-SMITH related a case showing unusual distribution of Secondary Cancer. The patient was a man aged fifty-eight, a spirit drinker, who was brought into Guy's Hospital with enlarged liver and mental disturbance. There was no vomiting or ascites. Jaundice came on soon after admission, accompanied by delirium, and he died comatose. He regarded it as a case of hypertrophic cirrhosis from drink. The liver was finely granular, tough, and fibrous; the spleen was enlarged. There was also a large malignant ulcerated growth in the posterior wall of the stomach, with a secondary large nodule in the liver, carcinomatous infiltration of the pancreas and secondary growths in the adrenal, thyroid, and lymphatic glands. There was also recent tubercle, with pulmonary gangrene and old tubercular changes in the apices of the lungs.—Dr. CHARLEWOOD TURNER had met with a case in which there was a

Digitized by Google

primary cancer of the rectum and secondary nodules in the ascending and transverse colon. But the latter growths were explained by the fact that the vermiform appendix had become adherent to the rectal tumour, and infiltrated with growth which had penetrated into the lumen, and so permitted the passage of cancer cells into the large gut. As to the causation of the pulmonary gangrene, though it might not have been due to feeding, yet it was difficult to exclude the possibility of eructations from the stomach having served as a causative factor.—Dr. PYE SMITH, in reply, said that the man did not vomit, and no particles of food could be discovered in the gangrenous part. The facts which he had brought forward went to confirm the view that every cancer had a single primary origin of purely local character, and the secondary growths arose by infection from the primary source.

Mr. EDGAR WILLETT showed a specimen of an Aneurysm of the Aorta in a child aged four. The sac, which was about the size of a walnut, lay in the concavity of the arch of the aorta, with which it communicated by a small opening situated at the termination of the descending portion of the arch. The pathology of this sac and its possible connexion with the ductus arteriosus were discussed, and microscopical sections of the walls were shown. Short clinical notes of the case were also given.—Mr. J. J. CLARKE had recently dissected for Dr. Phillips a specimen in which a caseous gland opened on the one hand into the left bronchus, and on the other into the aortic arch. The patient at first coughed up caseous matter, and later had attacks of hæmoptysis, one of which proved fatal. He showed a case in a child aged three of an aneurysm which appeared to result from inflamed lymphatic glands.

Dr. WALTER EDMUNDS showed a Cystic Adenoma of Kidney, which was removed during life from the body of a girl aged eighteen years. A movable lump in the left lumbar region had been noticed about two years, during which time it had appeared to grow. The tumour was thought to be the left kidney, and so on operation it proved to be. The patient did well. On examining the kidney after removal there was found projecting from its anterior surface a globular tumour; on section this was seen to be about two inches and a half in diameter, and to project internally into one of the calyces. The tumour consisted entirely of cysts of various sizes, the largest being about one inch in diameter. The cysts contained a thin colourless fluid, and were found on microscopic examination to be lined with an epithelium at places cubical, at others columnar. The remainder of the kidney was healthy, and was no doubt working at the time of removal. He had been unable to find either in the Transactions of the Society or elsewhere any record of a similar case; reasons had been given by Mr. Shattock in a paper read before this Society in 1886 (see volume xxxvii.) for thinking that in some cases of cystic disease of kidney the affection was due to the growth of included remains of the Wolffian body; the fact that the tumour was included in a distinct capsule seemed to favour that view in the present case. He was indebted to Mr. Croft, under whose care the patient was, for permission to exhibit the specimen.

The following card specimens were shown:—

Mr. E. WILLETT: Diphtheritic Membrane covering the greater part of the Mucous Membrane of the Stomach of a Child.

Dr. F. C. TURNER: Fibrous Atrophy of Right Adrenal: Hypertrophy of Left.

MEDICAL SOCIETY OF LONDON.

Further Cases illustrative of Hepatic Surgery.

AN ordinary meeting of this Society was held on April 4th, the President, Mr. Hutchinson, in the chair.

Mr. KNOWSLEY THORNTON read a communication on some further cases illustrative of Hepatic Surgery. The paper opened with brief notes of five cases of cholecystotomy, special attention being directed to the method best adapted to the suturing of the gall-bladder into the parietal wound, and to the various methods for dealing with stones when impacted either in the cystic or common ducts. The dilatation of the cystic duct advocated in a former communication was, as the result of larger experience, abandoned for a combination of needling and crushing *in situ* for small impacted stones, and duct incision and removal with subsequent suture of the duct in case of large stones. An interesting case of combination of stones and malignant disease of the gall-bladder (cause and effect) was described. Notes were then given of a probably unique case of removal of a sarcomatous growth from the inside of the cystic duct, and of two cases in which mere exploratory incisions were made, and the following summary of the conclusions arrived at by the author was given: 1. A properly conducted exploratory incision was free from risk, and might give valuable information leading to a scientific and successful after-treatment, even in cases in which no stone was found. Such exploration was, however, only justifiable after the most thorough trial of dietetic and medicinal treatment. 2. The ducts were as completely within the sphere of successful manipulative and operative treatment, when such were needful, as was the gall-bladder itself. 3 Stones of moderate size impacted in the ducts were better treated by needling and crushing, either by finger and thumb or by forceps pressure. Larger stones by incision, complete removal, and after-suture of the duct wall. 4. In cases in which débris was left in the ducts the gall-bladder should be opened, sutured into the abdominal incision, and drained. 5. In cases in which the ducts were incised and sutured a drainage-tube should be passed into the peritoneum beside the sutured duct, and the gall-bladder also drained externally. 6. In a well-marked case of repeated attacks of gall-stone colic, with recurring distension of the gall-bladder, it was better to operate early and before there was a chance of injury to the duct wall by impaction, and before the stone had reached the common duct. Such cases recovered rapidly, and there was every prospect that experience would show that complete intra-peritoneal suture of the wound in the gall-bladder would be safe and the rule of the future when operation preceded damage to the ducts from impaction.

The PRESIDENT remarked on the uniform success of the series. He himself had been much interested in the diagnosis of gall-stones and in estimating the amount and intensity of pain caused by them, and often referred to other causes. He had operated on only one case.

Dr. DOUGLAS POWELL said that the needling and manipulation of a stone in the duct were to him a novel procedure. Mr. Thornton seemed to regard the gall-bladder not as a reservoir for bile, but as a receptacle of fluid with which to wash out the bile-duct. He himself would like further evidence in support of this before accepting it, for it certainly impaired the value of some experiments which had been made as to the secreting function of the liver, seeing that the material used had been derived from the gall-bladder.

Dr. RALFE, though he admitted that surgeons had relieved physicians of many of these troublesome cases, yet held that there were instances in which it would be better if they waited longer before operating. In one case in which cholecystotomy was done the gall-bladder was found empty and cancer discovered to be present. In another case, in which operation was urgently recommended, the patient got well with rest and the use of mineral waters. Many attacks of so-called gall-stone colic were spurious and due to other causes, such as a collection of scybala at the hepatic flexure of the colon; or, as in one instance, the presence of a large round worm. Medical treatment should certainly be carefully tried before operative interference was thought of.

Mr. KEETLEY related a curious case that came under his care at the West London Hospital. A man had been ill six months, and had twenty attacks of biliary colic. He opened his abdomen and found the gall-bladder small and thickened; but careful palpation of both it and the ducts revealed no calculi. The patient made a rapid recovery, and gained strength. The hernia, which frequently developed at the site of the abdominal wound, was due to a want of correct apposition of the aponeuroses and fibrous elements of the abdominal walls one to another; cases left open for drainage were likely to prove defective in this respect.

Dr. BRISTOWE said that though medicine relieved the pain and promoted the passage of gall-stones in many instances, yet there were some in which he advocated the intervention of a surgeon. He related three cases of sharp attacks of colic in young persons in whom there was no jaundice, but who afterwards passed small stones. He referred to the case of an elderly gentleman who had an attack of gall-

Digitized by Google

stone colic accompanied by jaundice. The latter persisted for twelve months, at the end of which time there was a recurrence of colic, a gall-stone passed, and the patient recovered. A lady suffered a series of attacks of colic; after an attack laparotomy was performed, but no stone could be found. A young woman was attacked with hepatic colic and became seriously ill. At an exploratory laparotomy no stone could be detected, but the gall bladder was opened and stitched to the abdominal wall, and for some time after she passed all her bile that way. Later she died of profuse hæmorrhage in the deeper part of the wound; at the necropsy both the gall-bladder and the duct, before being opened, were carefully palpated by two or three observers, and nothing could be felt. Nevertheless on opening the common duct a calculus was found therein.

Mr. MARMADUKE SHEILD said that in the diagnosis of smaller abdominal tumours, such as gall-stone or movable kidney, it was necessary to submit the patients to a preliminary and thorough course of purgation. Gall-stones often existed without causing any symptom, and were very frequently found post mortem where they were by no means suspected. Abscesses of obscure formation, pointing in the right iliac fossa, at the umbilicus, or through the abdominal wall, often when they burst discharged a quantity of gall-stones. The case related, in which healing took place in spite of the fact that malignant disease of the gall-bladder was present, was interesting; but bones which fractured as the result of malignant disease would firmly unite, and so would the cut surfaces of a peritoneum which had undergone malignant infiltration. He asked what was the value of massage in cases of impacted gall-stone.

The PRESIDENT added that he could not accept the theory which had been put forth as to the function of the gall-bladder, for that structure in the fœtus was proportionately so very large. Although the Society highly appreciated the successes that had been recorded, yet he felt bound to enter a caution against any attempt at imitating these procedures among the profession generally. The public should not be taught to look upon gall-stones as substances which, like urinary calculi, when found ought to be removed. They were constantly found, for instance, in lunatics, especially melancholiacs, with no symptoms whatever. It was not the mere recognition of stones in the gall-bladder, but the suffering which patients endured from them, that should be the measure of the necessity for operation, and in this respect there was an essential difference between gall and urinary calculi; besides, they were all aware of cases which after operation had not proceeded to so happy a termination as those of the author seemed to have done. Perhaps a little later he would supplement the procedure of crushing the stone by flushing and washing out the fragments. In conclusion, he related the history of two females who had had gall-stones for as long as twenty years, and though they had suffered much from them at first, yet at present the symptoms had entirely subsided, although the calculi were still to be felt.

Mr. THORNTON, in reply, said that in his paper he had carefully defended himself from the assertion that he desired to operate on all biliary calculi. Though he agreed that in many cases they did no harm, yet against such cases were to be put others in which perforation and gangrene of the duct occurred, and the patient died in a few hours. It would be difficult to evacuate the crushed calculi, because one was dealing with a closed duct through which nothing could be washed, and which was therefore quite unlike a pervious urethra. He agreed that a thorough clearance of the intestines was necessary before arriving at a diagnosis. There was often no jaundice and no vomiting until the stone arrived in the common duct; but the case might prove fatal before this happened. He could not recommend massage as a method of treatment in these cases, for in two in which it was resorted to he found on operation that the stone had grown into the duct wall, and manipulation from without could only have ruptured the duct. Though occasionally cases could be met with which, after twelve months, had come to such a happy termination as that related by Dr. Bristowe, yet he doubted whether it would be right for a surgeon to wait beside a jaundiced patient for twelve months for the possibility of the stone moving. He related an instance in which he was unable to feel the presence of a stone which he afterwards found on opening the gall-bladder

EPIDEMIOLOGICAL SOCIETY.

The Bacteriology of Vaccine Lymph.

A MEETING of this Society was held on March 17th, Joseph Ewart, M.D., President, in the chair.

Dr. S. MONCKTON COPEMAN began by remarking that the determination of the nature and actual virus of vaccinia had hitherto baffled all inquiry; and that, notwithstanding the importance of the subject, the practice of vaccination was as yet empirical. Some, indeed, reflecting on the failure of all attempts at the extra-corporeal cultivation of the virus, had suggested that it was not an organism, but a chemical substance, or enzyme; and with the view to decide this question he had repeated the experiments of Cohn, Chauveau, and Burdon-Sanderson, from which they had concluded that the activity of the lymph resided in the solid particles rather than in the fluid portion. Dr. Copeman having obtained 2 cc. of calf lymph, diluted it with 4 cc. of a 50 per cent. solution of glycerine, which had the effect of increasing its fluidity and retarding coagulation during filtration, enhanced rather than otherwise its activity, or with a normal saline solution; using with strict antiseptic precautions a Kitasato's filter worked by an aspirator, he obtained filtrates absolutely free from all particles whatever. Inoculations of the filtrate on human beings and calves were uniformly unsuccessful; but the observation of Dr. Sidney Martin, in the course of his experiments with the anthrax bacillus, that if any of the alkali albumen in his artificial serum failed to be converted into albumose, it was retained in the filter, convinced him that these negative results were not conclusively confirmatory of the point at issue. He had himself found that while the serum, albumen, sugar, and salts of milk passed through a porcelain filter, the caseine as well as the oil globules were arrested, and it was therefore possible that a like proteid in the lymph, and not any of the particulate bodies, constituted the active principle, and that in the subsidence process of Chauveau and others it might have been carried down by the bacilli, so that neither the positive nor the negative results obtained under either procedure were conclusive in favour of the theories of Chauveau and Burdon-Sanderson on the one hand or of Cory on the other. In the hope of identifying the nature and action of the several bacteria, he next undertook a number of artificial culture experiments with calf lymph, sowing by both the "streak" and "stab" methods nutrient gelatines, agar-agar, and agar-agar with glycerine. These inoculations were invariably followed by luxuriant growths, the appearances of which he described, a feature common to all being that the parts of the growth most exposed to the air presented a marked colouration, more or less yellow or orange, especially in gelatine. Plate cultivations with portions of these masses enabled him to identify (1) micrococcus pyogenes aureus, (2) micrococcus cereus flavus, and (3) micrococcus albus or epidermis, results agreeing with those of Pfeiffer and apparently also of Buist. He also obtained an organism which he believed to be the streptococcus pyogenes. Inoculations with pure cultures of each of these on the human being, calf, and rabbits never produced more than the most trifling inflammation, and nothing in the least resembling vaccination, though one rabbit died apparently of septicæmia after a free inoculation with a mixture of all four. Thinking it possible that the luxuriant growth of these might have destroyed the specific organism, he sought by following the procedure by which Kitasato had successfully eliminated foreign microbes and isolated the bacillus of tetanus—viz., subjecting the tubes to a temperature of 60°C. for various periods, and making plate inoculations direct therefrom — to isolate in like manner that of vaccinia, but entirely without result. Inoculations of calves with lymph from the tubes thus treated and with fluid from the alkali albumen were equally unsuccessful, showing that the specific microbes, if any, had also been killed. After confirming Dr. Husband's observation that the activity of vaccine lymph was not impaired by exposure to a temperature of 33°C., Dr. Copeman found that the critical point was between 38° and 42°, and what was now wanted was the discovery of a suitable culture fluid. A remarkable result was, however, observed in the inoculation by Dr. Cory of a calf with lymph that had been heated to 48°. No vesiculation followed, but the animal proved refractory to subsequent

Those the luxuriant growth of these org the specific organism, he sought by the by which Kitasato had separated the crobes and isolated the bacillus of tetanus the tubes to a temperature of 98° C. nd making plate inoculations from isolate in like manner that of the ithout result. Inoculations of sterile m the tubes thus treated and with albumen were equally unsuccessful. specific microbes, if any, had also be ffirming Dr. Husband's observation f vaccine lymph was not impaired a temperature of 55° C., Dr. Copeman critical point was between 55° and now wanted was the discovery of a fluid. A remarkable result was in the inoculation by Dr. Cory of a been heated to 65°. No vesicle ...proved refreshing and

inoculations with fresh lymph of ascertained activity, showing that a degree of immunity had been conferred, possibly by the products of a microbe that had itself perished in a manner analogous to the experiments of Roux and Yersin with the products of the bacillus (Löffler's) of diphtheria. Such a method would of course preclude continuation by arm-to-arm vaccination, but it certainly seemed that lymph heated to 40° only, and thus freed from the organisms he had described, was considerably more energetic than fresh lymph, for the calf that, after inoculation with superheated lymph, had resisted the effects of fresh lymph of proved activity yielded to a subsequent inoculation with the lymph thus "purified," exhibiting five well-developed vesicles. Turning his attention next to the cloudiness that constantly appears in stored lymph, with impairment of its potency, Dr. Copeman put up a number of tubes, intentionally interrupting the lymph with air bubbles, and kept them for several weeks in a vertical position. Points of opacity appeared at the lower end of each separate column of lymph, showing that, though dependent on the access of air, the material of the opacity was heavier than the lymph, and subsided accordingly. It was not caused by coagulation, for the phenomenon was seen best in tubes the contents of which remained perfectly fluid throughout, and the white points in others were entangled in the fibrinous threads. Tube and secondary plate cultivations in gelatine with portions of this opaque substance showed it to be composed of aerobic organisms present in the lymph from the first, although in minute numbers. Careful exposure of the lymph to a regulated temperature checked or arrested the growth of these organisms, and thereby enhanced the potency of the lymph, but always involved the risk of overdoing it, and thus impairing its activity; but the desired result could always be attained by the simpler and safer procedure of dilution with a 50 per cent. solution of glycerine, even to the extent of twice or thrice its volume. Glycerine, which was well known to act injuriously on many pathogenic organisms, had evidently the effect of inhibiting the growth of these extraneous aerobes which not only gave rise to the familiar cloudiness, but tended to impair the activity of the lymph. Indeed, it was possible, though he could not speak with certainty, that in the presence of glycerine there was a positive increase of the specific organisms or active principle, and its employment was on every ground to be recommended as a means of securing better and more uniform results.

Staff Surgeon PRESTON, R.N., referred to the frequency with which lymph, carefully put up with boric or salicylic acids for exportation to the colonies, had been found on arrival to be quite inert, a result ascribed to the high temperature—viz, 96° F.—to which it had been subjected on the passage, to avoid which it was now forwarded to the China stations by the Pacific Railway, and endeavours were being made to keep up a supply of calf lymph in Australia. He asked whether light had any injurious effect on the activity of the virus. He had successfully used lymph that had been stored for two years or more, but the tubes had been kept in absolute darkness—viz., in clinical thermometer cases. He also wished to know if anything positive had been established as to the apparent mutual antagonism of vaccinia and syphilis, whether congenital or acquired.

Dr. HUNTER considered the presence of streptococci a very grave matter, since they were at least closely allied to those that gave rise to erysipelas and spreading inflammations. If the virus of vaccine were an enzyme it would doubtless bear without impairment a temperature of from 55° to 60° C., which would certainly kill all these microbes; otherwise it would, like other micro-organisms, perish at 45°, and glycerine offered the only means of keeping down these extraneous organisms.

Replying to questions by Sir W. Moore and Dr. Bulstrode, Dr. COPEMAN said that it was not quite correct to speak of "corpuscular" elements, for good lymph should contain no blood, or pus cells, or any leucocytes whatever. The extraneous microbes were not strictly aerobic, though they throve much better in the presence of air. Their numbers depended on the circumstances of its collection, but they were usually more numerous in calf lymph from the greater difficulty of securing cleanliness. The micrococcus epidermis, however, could not be wholly excluded, even by shaving and washing the skin with sublimate. It was now established that no bacteria existed in the fluids or tissues of the healthy body, and those present in the vesicles were the progeny of such as had been introduced with the lymph in the act of vaccination. Light acted injuriously on some, not on all pathogenic organisms, and probably on those of vaccine; but the failures referred to by Mr. Preston were more likely due to the antiseptics employed, for a temperature of 96° F. (36° C.) was certainly not high enough to produce such a result. The fact of the virus being reproduced in the living body through an indefinite series of transmissions was sufficient to prove that the active agent must be a living organism capable of self-multiplication. The immediate cause of the phenomena might indeed be, and probably was, as in other diseases, a product of the microbes, but it could not be merely a chemical substance the quantity of which must be limited. He admitted a certain apparent antagonism between vaccinia and syphilis, but the fact that they could be produced together by a single inoculation proved it to be very feeble. Erysipelas was, in the vast majority of instances, the result of subsequent infection from independent sources, the vaccination contributing nothing beyond the breach of surface for the entry of the microbe of erysipelas. Still, if by greater precautions in the operation and the selection of lymph and by the use of glycerine in storing it, these extraneous though ever present aerobic microbes, which, if they did not often set up unpleasant processes of an inflammatory nature, did certainly detract from the success of the operation and the completeness of the protection afforded, and still more if this elimination of all foreign organisms could be effected by exclusively artificial culture, the opposition to compulsory vaccination would be disarmed, if not entirely overcome.

HARVEIAN SOCIETY OF LONDON.

Transposition of Viscera.—Enlargement of Liver due to Chronic Hyperæmia.

A CLINICAL EVENING was held on March 17th, Dr. W. B. Cheadle in the chair.

The PRESIDENT exhibited cases of considerable clinical interest, the first being one of Transposition of the Viscera. He said that the patient, a boy of sixteen, had been admitted into the hospital with pleurisy and effusion into the left side. The position of the heart on the right side was at first attributed to mere displacement from this cause; as the fluid subsided, however, it became clear that this abnormal condition was due to transposition, the stomach, liver, and spleen being transposed in like manner. The transposition of the thoracic and abdominal organs was probably complete throughout. In every instance in which post-mortem examination had been made, and these points noted, this was found to be so. Not only is the heart on the right side, but its cavities and vessels reversed, and the right recurrent laryngeal nerve wound round the aortic arch instead of the left. The right lung has only two lobes; the left three. The liver lies on the left side, with its lobes reversed; the stomach on the right side, with the cardiac to the right, the pyloric extremity to the left. In the intestine the cæcum lies in the left iliac fossa, the sigmoid flexure on the right. The left kidney lies lower than the right; the right testicle lower than the left—the converse of the normal conditions. In one case the patient was left-handed, but in others normally right-handed, as in the present instance.

The two next cases were examples of Fibroid Enlargement of the Liver due to long-standing Chronic Hyperæmia. Dr. CHEADLE said that he brought them forward as illustrations of the special tendency in early life to rapid and profuse proliferation of the fibrous stroma under such conditions. The first of these two cases was that of a boy of twelve suffering from mitral incompetence, very probably also from thickened adherent pericardium and mediastinal fibrosis. The symptoms had been of that persistent and recurrent kind so characteristic of subacute pericarditis and mediastinitis in children—viz., persistent præcordial pain and moderate pyrexia of from 100° to 101°; rapid pulse of 100 to 140; constant cough and dyspnœa, without affection of the lung: all lasting, with slight remissions only, for several months, and accompanied by steady advance of cardiac dulness upwards and muffling of the heart sounds. A doubtful friction sound only was heard, but there was a loud mitral murmur. Some general dropsy followed, and the legs were tapped on the 14th of May last. As the liver engorgement and fibrosis advanced, ascites developed, and attained such proportions that the abdomen

Digitized by Google

was tapped six months later, on the 9th of November last, 240 ounces being drawn off. It was worthy of note that the fluid had not since returned either into cellular tissue or peritoneal cavity, so as to render a second tapping necessary, showing the value of early draining in such conditions. The case also illustrated the beneficial effect of opium in conditions of cardiac distress. Marked relief and improvement had followed its free use in this instance. There was an impression that the administration of opium in such cases was attended with danger, but it might be used without fear to relieve cardiac dyspnœa, unless the engorgement of lungs and cyanosis were extreme.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

Lumbago and Sciatica.

AN ordinary meeting of this Society was held on April 1st, the President, Dr. Chas. Wells, in the chair.

Mr. KEETLEY showed a girl aged twelve on whom he had performed partial Thyroidectomy for removal of a large fibro-cystic growth, and exhibited the specimen.

Dr. HERRINGHAM read a paper on Lumbago and Sciatica. He described a case in which lumbago had been accompanied by sciatica and by so-called rheumatic pains in the muscles of the shoulders and in the musculo-spiral nerve. He attributed this collection of symptoms not to a primary neuralgia, but to an affection of fibrous tissue involving the nerves by pressure, though he confessed that opportunities were so rare to examine the tissues post mortem that this view was rather an inference than an observation. The localisation of the disease was unexplained. Many other parts of the body, never affected, seemed quite as fitted by anatomical disposition to take on such morbid action—nor, indeed, was it clear why the sciatic nerve was so noxious to disease. Besides direct injury, as in parturition and probably in jolting, cold, damp, and indigestion, either the gastric or the constipating variety, were the only well-known causes. Of the twin means of treatment, preventive and curative, the former were by far the most valuable; of the latter, for lumbago he recommended strong purging above all others; for sciatica, rest, warmth, and patience. He thought that diet had little or no effect. He had had the opportunity of testing the excretion of uric acid, and had found that it had no connexion with the disease. Continuous regulation of the bowels he had found to be of great value. He concluded by citing cases of similar affections of other nerves, of the anterior crural, and of the brachial plexus.

Dr. SYMONS ECCLES read a paper on Sciatica, giving his experiences of fifty-two cases treated by combined rest and massage. He divided his cases into three groups: 1. Those with long-standing lumbo-sacral pain; in ten of these cases constipation seemed to be the exciting cause. 2. Peri-neuritis with "tender points," but without any vaso-motor changes. 3. Neuritis, in which there were evidences of trophic dyscrasia. The loss of knee-jerk noted by some he thought to be apparent rather than real, and due to subjective disinclination to excite an exacerbation of pain. He had noted pelvic visceral disease and sigmoid constipation as causes of this painful condition. He pointed out the importance of guarding against chill, and advocated the use of warm woollen underclothing by day and night. In conclusion, the author claimed the scientific use of massage and galvanism (from ten to fifteen milliampères) as a valuable means of cure.

MANCHESTER MEDICAL SOCIETY.

WEDNESDAY, MARCH 16TH.

Mr. A. W. STOKES, President.

Venous Pulsation.—Dr. MACKENZIE (Burnley) gave a demonstration of a means of graphically recording pulsation in the veins, whereby the movement of the apex beat or carotid pulse could be employed to time the events occurring in the veins. The essential features in the method were the covering of the vein or other pulsating part with a small leaden funnel. This funnel was connected by an elastic tube with a tambour, the lever resting on which recorded the movements communicated by the vein on the smoked paper of a revolving cylinder or Dudgeon's sphygmograph. The veins of which the pulsations were recorded were mostly the internal jugular, but tracings were also shown from the axillary vein, the femoral vein, and from the liver. The conclusions arrived at from the consideration of a large number of cases were summarised as follows:—Pulsation in the veins arises when from any cause dilatation of the right heart and great veins, with incompetency of the tricuspid and venous valves, takes place. While the auricle can vigorously contract there is a wave synchronous in time with and caused by the auricular systole (auricular wave). When the dilatation of the heart and veins is moderate, the auricular wave is followed by a great depression synchronous with and caused by the auricular diastole (auricular depression). In most cases there is a wave produced by and synchronous with the latter portion of the ventricular contraction (ventricular wave). The greater the incompetence of the tricuspid valve and the greater the distension of the auricle, the earlier does the ventricular wave appear, and the larger space of time it occupies. The ventricular wave in cases of extreme dilatation of the right heart may occupy the whole period of ventricular systole; the depression caused by the auricular diastole is then replaced by the ventricular wave. In such rare cases the auricle has ceased to contract independently, or its contraction is represented by a very small wave preceding the ventricular wave. The great depression then shown in tracings of the venous pulse is caused by and synchronous with the ventricular diastole (ventricular depression).

MIDLAND MEDICAL SOCIETY.

WEDNESDAY, FEB. 27TH.

Mr. BENNETT MAY, F.R.C.S., President, in the chair.

Mr. CHAVASSE showed a case of Nævus Pilosus occupying the entire half of the face in a girl seventeen years of age. The hair on the scalp of the affected side was thicker, coarser, and of a darker colour than on the normal side. Although congenital and progressive, the parents had not permitted any steps to be taken to retard the growth. Mr. Chavasse also showed an Alveolar Sarcoma occurring in the cicatrix of a shoulder-joint amputation undertaken eight months before for a mixed-celled growth in the lower third of the arm, the patient being a man aged fifty-three. To effectually remove the infiltrated tissues it was necessary to resort to Berger's method of dealing with the subclavian vessels and removing the scapula and two-thirds of the clavicle.

Vesical and Renal Calculi removed from the same Patient. Mr. F. MARSH exhibited five calculi, two of which, weighing fifty-two grains, he had removed from the bladder on Jan. 29th, 1891, and three, weighing fifty-four grains, from the right kidney on Feb. 11th, 1892, of a man aged twenty. According to the patient's statement the symptoms were of about seventeen years' duration. When about three years old he suffered from pain in the right loin, with hæmaturia and increased frequency of micturition. The pain had been almost constant ever since, was worse after exercise, and sometimes shot downwards. The hæmaturia and increased frequency of micturition were intermittent; the former was well marked, and usually lasted for from ten to fourteen days. When he was fourteen years old the hæmaturia ceased. He has had no distinct attacks of renal colic. When he came to the Queen's Hospital in January, 1891, he had symptoms pointing to calculus both in the bladder and right kidney. He was admitted, and the vesical calculi were removed by suprapubic lithotomy, the wound healing in ten days. The calculi were chiefly composed of urates, and the smaller one did not appear to have been long in the bladder. The man was therefore advised to wait for a time before having the kidney exposed. When he came again to the hospital, in December, 1891, he still had the renal symptoms and was also suffering from frequent seminal emissions, which was really the reason of his attendance at the hospital. He was treated for this for a short time and then admitted with a view to nephrotomy, but a suppurative inflammation of the right middle ear developing, the operation was postponed for a few weeks until this was cured. During this time the urine was repeatedly examined, and occasionally a few pus-cells were seen, but never any blood-cells or crystals; the percentage of urea was normal. Percussion or

Digitized by Google

pressure over the right kidney always caused pain, more marked on the anterior than on the posterior surface. No pain could be elicited by manipulation of the left side. There was no clear history of renal colic. Right lumbar nephro-lithotomy was performed on Feb. 11th, 1892. One calculus was felt embedded in the kidney tissue on the anterior surface and removed by an incision directly over it. It was about the size and shape of a small marble covered with little spikes, and was probably the cause of much of the pain. The second (the largest) and the third (the smallest) were removed respectively from a calyx and the pelvis by a fresh incision through the kidney substance. The first stone was composed almost entirely of oxalate of lime, and the two others chiefly of urates, the third one having a striking resemblance to the smaller one found in the bladder. The different layers of muscles were carefully approximated by buried sutures of silkworm-gut. A drainage-tube was inserted down to the kidney for forty-eight hours. The wound healed by first intention, no urine coming through it. For a week a fair amount of blood was passed with the urine; it then became clear, and the average daily amount since passed has been approximately forty ounces.

Mr. EALES showed a man aged twenty-four years who had a Sinus opening through the Upper Lid close to the nose and reaching in a direction almost directly backwards for about two inches. Fluid injected into the sinus came down into the nose. Mr. Eales stated that this man first came under his notice on Feb. 17th complaining that in a brawl on Dec. 8th he had been struck by another man who had his pipe in his hand when he struck at him, and that ever since the sinus had existed and would not heal. He was at once put under chloroform, the opening of the sinus enlarged and examined, when a hard substance was found and extracted by forceps, which on examination proved to be the vulcanite mouthpiece of a tobacco-pipe, broken off and measuring exactly two inches in length. Mr. Eales likewise showed a lad aged thirteen who was suffering from a Ruptured Globe. The lens was displaced into the vitreous. The retina was detached (T = − 2) and the sclerotic was ruptured below for a considerable extent about the equator, the anterior parts of the eye being unruptured.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

THURSDAY, MARCH 24TH.

Mr. W. F. FAVELL, M.R.C.S., President, in the chair.

DR. CLEAVER showed a specimen of Arrested Development of the Œsophagus from an otherwise healthy male infant, born at full term. As the child was unable to swallow, an unsuccessful attempt was made to pass a catheter down the œsophagus, and thus inject the milk. The child lived for six days and a half. On post-mortem examination, the œsophagus was found to end in a cul-de-sac at the level of the bifurcation of the trachea, from which point it was continued to the stomach as a mere membranous structure.

Mr. T. ROBINSON showed a female patient with "Argyria." Nitrate of silver had been prescribed six years before for sickness connected with uterine disease. She had taken it at first for about twelve months, and four years later she again took it for three months, of her own accord, for similar symptoms. Altogether she took about 340 grains of nitrate of silver. The discolouration, which only became marked after the second administration, was confined to the face almost entirely, the exposed part of the conjunctiva being slightly tinged. There was no blue line on the gums.

Dr. HUGH RHODES showed for Mr. A. JACKSON a case of Charcot's Disease of the shoulder and knee in a man aged sixty-two. There was a history of syphilis at seventeen years of age. The illness began seven years before with lightning pains, gastric crises, and increasing ataxia, which spread from the legs to the arms. The shoulder became diseased six years before, and the knee four years later. Both joints were very typical examples of Charcot's disease, the mobility, especially in the shoulder, being increased, and the onset of the affection nearly painless. Much of the shaft of the humerus was worn away, and the head of the bone could be put into the position of nearly all the dislocations. The circumference of the knee was four inches greater than that of the opposite joint. There was effusion into both joints, and the articular surfaces were eroded and grating.

Mr. C. ATKIN also showed a man with old-standing Charcot's Disease of the knee, who had been shown to the Society some years before.

Dr. BURGESS showed two cases of Friedreich's Disease. One a girl aged twelve, with marked tabeto-cerebellar gait, swaying of the trunk, and slow nodding of the head. Superficial reflexes present; knee-jerks absent. No ataxia of the arms; speech unaffected. The difficulty in walking was first noticed four years before, after an attack of scarlet fever. The patient was the eldest of the family living, and none of her brothers and sisters were similarly affected. The other patient was a man aged twenty-six, with ataxic gait, nodding of the head, twitching of the mouth, and distinct affection of the speech. A sister was said to be similarly affected. Superficial and deep reflexes were exaggerated. Both feet were high-arched, with claw-like condition of the toes and prominent extensor tendons. There was no pain or any sensory disorder; no evidence of syphilis. He first noticed that he staggered in the dark four years before, and had gradually become more and more unsteady. For the last three years he had found it an effort to talk. A shoemaker by trade, he had found difficulty in aiming with his hammer for the past two years.

Mr. R. J. PYE-SMITH read a paper on the Disposal of the Dead. He contended that the altered conditions of modern town life, as well as the dangers of our present system of burial, required a reconsideration of this question. The encasing of the body in a wooden coffin and burying it deep in the earth or in a vault he characterised as the worst possible compromise between the antagonistic aims of preserving a body as long as possible and of hastening its disintegration. He maintained that the substitution of a perishable coffin of *papier mâché*, or of paper covering a light iron tray and frame, would prevent the pollution of air and water; and that burial at a depth of nine feet in cases of infectious disease would be an effective check to their danger. On this point he referred to the observations of Darwin and Pasteur, showing that earth-worms, by the medium of which such diseases might be transmitted, never burrowed deeper than eight feet from the surface; also quoting Flügge to prove that few pathogenic bacteria could grow in the cold earth, and that both soil and air had a direct influence in preventing the formation of ptomaines. He further referred to Dr. Poore's experiments on the filtration of urine as indicating the small risk to the watercourses from earth-to-earth burial. Mr. Pye-Smith advocated shallow graves, the systematic planting of trees, shrubs, and flowers, and no reinterment in the same spot within at least twenty-five years. Finally, as an argument in favour of rational interment rather than cremation, he urged that nature needed the products of animal decay for the growth of the vegetable kingdom, on which we in turn depended for our sustenance and wealth.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.

WEDNESDAY, MARCH 16TH.

Mr. ANDERSON, F.R.C.S., President, in the chair.

Operation in Chronic Intestinal Obstruction.—Mr. GRAY read a paper on this subject. He related four cases, in the first of which the symptoms were acute; but, as the result showed, there was no real obstruction. In the other three cases there was an acute attack following symptoms pointing to obstruction, varying from six months to ten years in duration. In two cases a band was found post mortem, under which a large quantity of small intestine was partially strangulated; in one case the band was peritoneal, and in the other formed by adherent small intestine. The four cases were contrasted to show the difficulty of deciding when to give up ordinary measures and when to advise operation in the face of apparent improvement. Stress was laid on the inadvisability of giving opium until the diagnosis was made, in consequence of its tendency to mask symptoms. The operation of laparotomy was described, and the recommendation given to commence the search for the obstructed portion by following the course of the empty coils of intestine lying in the pelvis. The causes of the

Digitized by Google

high mortality of these operations were discussed, and a parallel drawn between them and herniotomy. The opinion was expressed that when laparotomy came to be looked upon as a primary measure instead of a last resource the mortality would fall nearly to the level of that of herniotomy.

Dr. HANDFORD showed a patient suffering from Intermittent Albuminuria with general vascular sclerosis, who had been greatly benefited by treatment with iodide of potassium.

Reviews and Notices of Books.

Lectures on Pathology. Delivered at the London Hospital by the late HENRY GAWEN SUTTON, M.B., F.R.C.P. Edited by MAURICE EDEN PAUL, M.D., and Revised by SAMUEL WILKS, M.D., LL.D., F.R.S. London: J. & A. Churchill. 1891.

WHEN, five years ago, a small volume of the late Dr. Sutton's lectures was published, the work, notwithstanding certain blemishes in composition, attracted universal attention for the freshness of style, the originality of conception, and the profundity of thought that were evinced in it. Never before had the prosaic subject of morbid states been dealt with in so entrancing a manner, and all who read it must have envied the students who sat at the feet of a master whose descriptions of disease were accompanied by suggestions and practical inferences that could not fail to rivet attention and excite admiration. It must be borne in mind that these lectures, which are incorporated in the present much enlarged and more carefully edited volume, were transcribed as they were orally delivered, so that, although some objection may be taken to their discursive character, they represent faithfully the spoken words and the thoughts which seemed to rise in the lecturer's mind as he passed from topic to topic. By means of the additions now made, the text embraces nearly the whole range of diseases; but it must not be supposed that it is exhaustive in the sense of anatomical description. Dr. Sutton recognised that the word "pathology" embraces much more than mere anatomy, and he included in his purview questions of etiology, of bedside observation, and of therapeutical measures, when considering the disorders of function which are linked with anatomical lesions. Herein rests one great charm of these lectures, which mark the liberation of the *rôle* of teacher from the limits imposed by the ordinary text book or by the examining board. We can imagine how the student must have looked forward to a lecture which did not aim at reproducing in routine fashion and orderly array the facts of pathological investigation, but which served to explain and illustrate the lessons learnt in the ward and post-mortem room by reference to a wide experience and the results of deep reflection.

The volume, however, will, we imagine, be even more highly valued by those already engaged in practice, since it embodies the views of a physician who had freed himself from the trammels of tradition, and who, in his dealings with disease, always held in view the natural physiological laws that govern the body in health, so that he laid more stress upon the leading principles of rest and nutrition than upon the results of pharmacological researches in promoting restoration to health. It may be that Dr. Sutton's wide pathological knowledge led him to depreciate the value of drug treatment; but those who study his words will see that he does not discard this altogether, but reserves it for those conditions where the direct influence of remedies is obvious. He knew well that the patient requires *advice* as much as, and more often perhaps than, medicine; and one cannot wonder that such a man, who always had before him the possibilities of recuperation that lie latent in the organism, should become a successful practitioner. We will not anticipate the pleasure which every reader of this book will gain from its perusal by citing passages from it here, although it would not be difficult to select many which for terseness and force deserve to be remembered as aphorisms; whilst there are other sayings which at first seem to run counter to all the reader's cherished opinions, although on reflection they may be found to contain truths of great value. In a word, we are very grateful to the friends and pupils who have furthered this publication; and in closing a book which no one who has read once will fail to return to again and again, we cannot but regret that so acute and philosophical an observer has not left behind him more of the products of his fertile mind to instruct and delight posterity.

Essays on Acromegaly. By Dr. PIERRE MARIE and Dr. SOUZA LEITE. With Bibliography and Appendix of Cases by other Authors. London: The New Sydenham Society. 1891.

ACROMEGALY was the term applied to a pathological condition by Dr. Pierre Marie, who first clearly identified it, and whose essay is given in this volume. It belongs to the class of affections which produce such a striking change in the conformation of the body as to be recognisable at first sight; and it is characterised by a giant-like overgrowth of the peripheral parts of the body, the bony framework as well as the soft tissues. So striking is this progressive alteration in the frame that it is singular it should have been identified as a distinct condition only some seven years ago; but the bibliography and records contained in this volume (which is edited and translated by Mr. Procter Hutchinson) comprise, in addition to the writings of Marie and Souza-Leite, several cases which were recorded years before these essays appeared. It is interesting to note that one of the earliest of these is a case brought before the Pathological Society in 1857 by the late Mr. Oliver Chalk under the title of "Partial Dislocation of the Lower Jaw from an Enlarged Tongue." This case, which seems undoubtedly one of acromegaly, was further remarkable from the fact that the changes commenced in quite early life, and at the time of its record the face was much elongated by the hypertrophy of the lower jaw, which projected about an inch in front of the upper jaw; whilst the tongue occasionally protruded for some distance beyond the line of the teeth. Mr. Hutchinson has added to the cases collected by Dr. Souza-Leite notes of those published since the date of that essay, so that the volume contains practically all that has been written on the subject. One feature of singular interest is the fact that in nearly all the cases examined after death (and they are but few) the pituitary body has been found greatly enlarged. There is no doubt that this publication will stimulate inquiry into the subject and probably result in many additional cases being brought to light. There is, unfortunately, one blemish in the book, and that is the roughness and indistinctness of the woodcuts, which have been reproduced from old blocks, and are quite unworthy of the text.

Studies in Anatomy in the Anatomical Department of the Owens College. Vol. I. Manchester: Cornish. 1891.

PROFESSOR A. H. YOUNG has collected and edited a large number of papers containing original researches in anatomy conducted by himself and his demonstrators during the past three or four years. Some of the papers have not been previously published, whilst others are reprinted from the "Journal of Anatomy and Physiology," and other publications. The most important of the unpublished investigations are those of Professor Young on the Termination of

Digitized by Google

the Mammalian Aorta, with Observations on the Homologies of the Pelvic Arteries; of Dr. A. Robinson on the Development of the Posterior Columnæ, the Posterior Fissure, and of the Central Canal of the Spinal Cord, and on Abnormalities of the Venous System and their relation to the Development of Veins. These papers are of considerable importance, and of great interest to the anatomist, and are well illustrated. Mr. J. W. Smith, in an account of Some Muscular Anomalies in Human Anatomy, describes an instance of complete absence of the sterno-hyoid muscle on both sides in a female subject, who presented many other irregularities in the muscular system; he also discusses several important variations of the well-known "achselbogen" and "sternalis" muscles with regard to their derivation and innervation. The volume shows how ably and thoroughly anatomical research is carried on at Owens College, and Professor Young must be congratulated on being able to publish such a series of valuable investigations.

OUR LIBRARY TABLE.

Die Menschliche Stimme nach Charles Lunn's "Philosophy of Voice." Von LUDWIG J. TRÜG. Pp. 124. Düsseldorf: L. Schwann. 1892.—Charles Lunn was a singer with a fine tenor voice, who established a School of Music in Birmingham in 1866, the teaching in which was highly esteemed by experts both in England and abroad. The method adopted was that of the old Italian school. The present work is an attempt to resuscitate it. The author commences by giving directions as to the mode of breathing to secure the best results, and a slight sketch of the anatomy of the larynx. The following sections describe the different registers, the relations of the male to the female voice, the theory of the voice, and the mode in which it may be exercised and strengthened. It is comforting to know that so few sing well, not because they do not possess a properly constructed organ, but because they do not educate it. The translation appears to be correctly done.

Tuberculosis and its Successful Treatment. By ROBERT BELL, M.D., F.F.P.S., &c. Glasgow: David Bryce and Son.—This essay is intended to show that the proper line of treatment of infective disease in general, and of tuberculosis in particular, is to afford support to the vitality of the tissue cells of the invaded organism; and it is therefore based largely upon the acceptance of the truth of the doctrine of phagocytosis. It constitutes also a plea for the prescription of muriate of calcium in tubercular diseases, the continued use of which has, in the author's hands, served to confirm his former experience as to its efficacy. He criticises adversely the treatment by tuberculin, and maintains that the simplicity of the remedy he advocates should be no bar to its more general employment. In this opinion no one will venture to differ with him.

Electricity Up to Date. By JOHN B. VERITY. London and New York: Frederick Warne & Co.—This little book deals in a popular and instructive way with the more practical problems of electric lighting and electric power. The author tells us in his preface that his object has been to write for the general public, and therefore with as much freedom from technicality as his subject would allow. Upon the whole he has succeeded, and succeeded well. Admirable features of his book are an excellently selected glossary and a carefully compiled index. His choice of subject is also marked by sound judgment, and his exposition is usually both clear and concise. Occasionally, however, he slips into inaccuracy or confusion. For example, on p. 50 he explains the danger from access of moisture to electric cables to be that the copper wires might become wet. Now, this would matter nothing whatever if the insulator remained intact. It is because a film of moisture connects the copper wire with the outer world that leakage takes place, and the absence of this suggestion from the passage in question makes what was no doubt as clear as day to the writer's mind almost unintelligible to the ordinary reader. But such shortcomings are only faults which a revising hand would easily remove or repair.

Bradshaw's Dictionary of Mineral Waters, Climatic Health Resorts, Sea Baths, and Hydropathic Establishments. With Maps and Plans. London: Kegan Paul, Trench, Trübner, and Co. 1892.—This is too good a book to be disfigured and have its usefulness impaired by misprints; but of these, we are sorry to say, there are not a few. Though professing to be revised up to 1892, the list of "specialists," which would be much better omitted, includes the name of Sir William Gull, who is no more; while Dr. Graily Hewitt will hardly recognise himself as "Dr. Hewitt Grail," or the well-known Florentine consultant in skin diseases as Dr. "Pellizari." The list of practitioners at the chief continental towns and healthy results is equally faulty, Drs. Aitken and Grigor, for example, being represented as now practising at Rome, though both of them have been dead these five years and more; while Dr. Spurway, who has taken the place of one of them in that capital, is referred to as still in practice at Pegli. Among the African health resorts why is the insanitary Tunis mentioned and the delightful Biskra, on the borders of the Sahara, ignored, the latter, moreover, being quite as well favoured in sulphur springs as the former, while infinitely superior to it in climatic steadiness, natural beauty, and repose? Montecatini, in Tuscany, has, we find, bad justice done to it in this edition, so far as its highly efficacious saline waters are concerned; but why restrict its medical staff to Dr. Paolo Casciani (whose name is also misspelt, by the way), and not include the eminent head of the establishment, Professor Federici, and his colleague Dr. Pio Fedeli? Amid blunders and defects such as these, what confidence has the reader that the temperatures of the several springs are correctly given or that the other indications are sufficiently accurate to spare him a fruitless and expensive journey? The book, we repeat, is distinctly meritorious in the main, but if it aspires to keep up its popularity it must for the future be less perfunctorily edited.

Epsom College Natural History Society. Report for the year ending Christmas, 1891.—The third number of this report recommends itself in a marked degree to favourable criticism. Compared with the attenuated nature of its two predecessors, its sudden growth to over a hundred pages appears very remarkable. But there is more than mere growth to note; there is internal evidence of healthy development, and this, again, affords the best testimony of real work. Although it is somewhat regrettable that no regular meetings were held in the geological or entomological sections of the Society during the midsummer term, they have not been entirely neglected. The lecture on the venomous snakes of India by Sir Joseph Fayrer is reproduced, and forms a highly interesting section. That on the wild animals of India by the same lecturer must also have afforded much satisfaction and instruction to the members of the Society. The reports of the various sections afford evidence of very useful work.

AN INFECTIOUS HOSPITAL, LEEDS.—The sanitary committee of the corporation has agreed (subject to a contract to be prepared to the satisfaction of the town clerk) to purchase the Manston Hall estate, situated in the York-road, for the sum of £10,000, for the purpose of erecting on the estate a hospital for infectious diseases. The property comprises upwards of ninety-seven acres and a mansion.

Analytical Records.

TOLPHITE.

(W. R. & H. V. DODD, 2, ST. ANDREW'S-PAVEMENT, STAMFORD-HILL.)

Qualitative analysis soon reveals the constituents which compose this nursery powder. It is perfectly free from all irritants, is antiseptic, carefully pulverised, and has a soft micaceous feel when rubbed between the fingers. All these are qualities which recommend it for the purpose for which it is intended.

BELLARA: AUSTRALIAN WINE.

(J. R. B. EARNSHAW & CO., SUFFOLK HOUSE, LAURENCE POUNTNEY-HILL, CANNON-STREET, E.C.)

It is now generally conceded that the wines exported from our big colony Australia are really of an excellent kind, and, though "cheap," are by no means "nasty." From the following analysis of Bellara claret, some idea of its composition may be gained: Alcohol, 8·85 per cent. by weight, 10·95 per cent. by volume; total solid matter 2·96 per cent., mineral matter 0·30 per cent. It is an agreeable light wine, free from excess of acid, and well suited for table use.

HALL'S COCA WINE.

(STEPHEN SMITH AND CO., BOW, E.)

This is an excellent wine, with an alcoholic strength equal to good port, possessing a similar flavour and bouquet, but associated with it also is the peculiar though pleasant aroma of the fresh coca leaf. Ether when shaken with the alkalised wine yielded a residue on evaporation which with hydrochloric acid gave characteristic crystals of cocaine hydrochlorate; they were further identified by the numbing effect produced by the crystals when rubbed on the tip of the tongue. Analysis gave the following data: Alcohol 15 per cent. by weight, 18·50 per cent. by volume; total solid matter 18·73 per cent. (sugar and coca principles), mineral matter 0·33 per cent. The restorative and invigorating properties of the coca leaf are now well known, and it may be very conveniently and palatably administered in the form of an agreeable wine such as that under examination, a wineglassful of which is stated to contain one drachm of the soluble active ingredients of the leaves.

PUREST CHLOROFORM.

(SALAMON AND CO., RAINHAM, ESSEX.)

No exception can be taken to the bold name of this product in view of the excellent results it furnished on examination. It distilled over almost to the last drop at 60° to 61° C., and left no residue. A trace of alcohol was detected by the exceedingly delicate iodoform test, and the specific gravity at 15·5° C. was accordingly found to be 1·4966. If the pharmacopœia tests for aldehyde, ketone, chlorine, and acidity are to be relied upon, none of these impurities are present. We have not examined a purer specimen.

NIEMANN'S CARNINE SYRUP.

(J. H. NIEMANN AND CO., AND R. F. MACLOSKEY, 12, MAJOR-STREET, MANCHESTER.)

To preserve the fresh juice of uncooked beef without sacrificing its specific qualities and without introducing antiseptics, the presence of which in a preparation destined for the most part for invalids is undesirable, has often proved a difficulty. Least objectionable of preservatives, and one hitherto unthought of apparently, is cane sugar. The above preparation is made by simply mixing sugar with the juice expressed by hydraulic pressure from raw meat. The result is literally a sweetmeat, nutritive, and palatable, and one that can be readily and agreeably taken in aerated water or milk. One fluid ounce of the syrup according to our experiments results, when boiled, in the coagulation of no less than eleven grains of solid albuminous principles. It contains also nitrogenous matters in a soluble and non-coagulable form. The preparation is a new and important addition to the list of valuable nutrients.

CORALLINE.

(THE CORALLINE MANUFACTURING COMPANY, E.C.)

Coralline, like many kindred preparations, is simply the flour of a certain cereal, moulded into attractive shapes by suitable treatment with steam, or other means. The microscope indicated at once the kind of starch of which it is largely composed. It is a cooked food, and will be found useful for the preparation of palatable diet for children.

PEARL-COATED PILLS AND LANADEPS.

(T. HOWARD, LLOYD, & CO., 86, HIGH-STREET, LEICESTER.)

Five specimens of pills, elegantly coated with a composition which in appearance resembles pearl, have been submitted to us by this firm. The coating gradually disintegrates in flakes even when placed in cold water, and the medicament is soon exposed in an excellent state of preservation, as was indicated by an analysis of the Blaud pill. Lanadeps is the name of a valuable ointment basis prepared from sheep's wool. It does not saponify readily with alkalies, is free from irritant fatty acids, and does not undergo an undesirable change on continued exposure. Lanadeps according to our experiments absorbs over half its weight of water. It is therefore admirably adapted as a vehicle for the external application of drugs like mercurials, iodoform, or potassium iodide.

HOLLANDS GENEVA (J. D. K. & Z.).

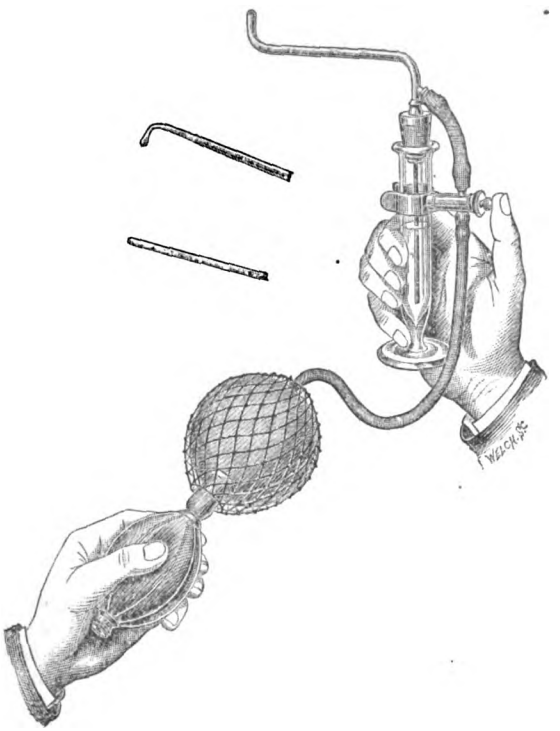
(JOHN DE KUYPER AND SONS, ROTTERDAM.)

A carefully distilled spirit, characterised by the peculiar flavour and smell which betoken the genuine Schiedam of Holland. Unlike most other spirits, hollands is practically free from solid matter and extractives, and on this account it may in some cases be advantageously substituted for the more popular whisky. The following analysis testifies in a measure to the unquestionable purity of this spirit: Alcohol, 42 per cent. by weight, 49·45 per cent. by volume—equal to 86·7 per cent. proof spirit; extractives, 0·032 per cent.; mineral matter, 0·015 per cent. Owing to the presence of a small quantity of essential oils, the spirit, on dilution with water, yields a slight opalescence, which is immediately cleared on the addition of ether.

GLYCERINUM PEPTICUM.

(BURROUGHS, WELLCOME, AND CO., SNOW-HILL BUILDINGS, E.C.)

In our experiments this convenient preparation gave very satisfactory results. A few drops, for instance, diluted with very weak hydrochloric acid, rapidly digested a thin slice of hard-boiled white of egg, and in a short time dissolved it completely. The resulting solution gave the well-known biuret reaction for peptones. The preparation is simply a solution of pure pepsin in glycerine, and contains no objectionable antiseptics; it is trustworthy, and may be relied upon for uniformity of digestive power. The ease, also, with which it can be dispensed is clearly an advantage of some importance to practitioners.



New Inventions.

SPRAY PRODUCER, WITH CHECK ACTION FOR APPLYING MEDICAMENTS TO THE LARYNX &c.

THE merits of this instrument will be likely to be appreciated by those who have used the old form of spray, which allows a cloud of vapour to generate as soon as the bellows are worked, thus obstructing the surgeon's view. The instrument illustrated below allows the bellows to be fully charged with air, but does not set the spray working until the surgeon has focused the exact spot desired to be operated on; then, by touching the tap, he can start or

Digitized by Google

stop the spray instantly. Application by this means is rendered more effectual, and a nervous patient will be saved the discomfort arising from the hissing of the instrument before it is introduced into the mouth. Three tubes fit

each bottle as figured above. The apparatus is manufactured by Walters and Co, 29, Moorgate-street, London, E.C.

AN AUTOMETRIC STOPPER.

MESSRS. FLETCHER, FLETCHER, AND STEVENSON have submitted to us a simple and ingenious device by which the measurement of liquid medicaments is not only facilitated but made more accurate. It consists, as a glance at the accompanying sketch will probably explain, of a stopper made of pure unvulcanised rubber, in which is fitted a strong glass pipette graduated in five-minim divisions up to 120 minims. At the top of the pipette, just above the rubber cork, a rubber air-ball is attached, which, fitting closely to the perforated cork, gives the whole design the appearance of a common decanter stopper. On removing the stopper and attachment, and slightly compressing the ball, the required volume of liquid can be easily withdrawn, and then transferred to the bottle which is to contain the medicine. The "autometric stopper," as it is aptly called, is supplied with the 1 lb. bottles of this firm containing their "concentrated liquors."

SERGEANT'S VAPOUR INHALER.

THIS apparatus consists of a thin glass test-tube closed with a perforated cork, through which passes a small glass tube. To this can be attached a mouth-piece or a nose-piece. By its use volatile drugs, such as menthol and eucalyptus oil, can be brought into immediate contact with the throat and nasal passages in a heated state, by plunging the test-tube into some hot water and inhaling the medicament. It is manufactured by F. Ross Sergeant, Market-place, Nottingham.

INDEMNITY FOR CERTIFYING LUNATICS.

To the Editors of THE LANCET.

SIRS,—We are directed by the Council of the Medical Defence Union to lay before you the enclosed opinion of the legal advisers of the Union, which forms their reply to a question addressed to them as to the validity of a written indemnity obtained from the friends of a patient certified to be of unsound mind. It is thought that the information may be of general use to members of the profession.

We are, Sirs, your obedient servants,

LESLIE PHILLIPS, } Hon. Secs, Medical
A. G. BATEMAN, } Defence Union, Ltd.

Birmingham, March 29th, 1892.

Indemnity for Medical Certificate.

March 11, 1892.

DEAR SIR,—The provisions of Sec. 330 of the Lunacy Act, 1890, afford such ample protection that any attempt to extend them might be construed as an incentive to carelessness, if not worse, in the signing of medical certificates in lunacy. At the same time it is obvious that, notwithstanding the protection afforded by the section, a medical man, who, we suppose, receives but a small fee for certifying, might be put to a considerable amount of expense in defending himself against ill-founded proceedings.

We have, in accordance with your request, drafted a form of indemnity which we think is not open to objection on the ground of it being against public policy or otherwise In case you should now or hereafter find it worth while to have printed forms of such an indemnity, we suggest that on the back of the indemnity a copy of Section 330 should be printed in accordance with the enclosed. JOHNSON & CO.

("I" or "We") hereby request you to sign a medical certificate that.....is a person of unsound mind, in accordance with your verbal report to ("me" or "us") to that effect, as the result of your examination of the said.....

And ("I" or "we, jointly and severally") hereby undertake to indemnify you against all liabilities, costs, and expenses, of what kind soever, to which you may be rendered liable, or which you may reasonably incur in consequence of any proceedings which may be threatened or instituted against you by reason of your having signed such a certificate, if in such proceedings it shall be admitted or proved that in so doing you acted in good faith and with reasonable care, in accordance with the provisions of the Lunacy Act, 1890 (53 Vict., c. 5), or such proceedings shall be discontinued or not proceeded with.

Dated this day of , 189 .

Witness to the signature of the said.....
Name .....
Address .....

Section 330 of the Lunacy Act, 1890 (53 Vict., c. 5), is as follows:—

1. A person who before the passing of this Act has signed or carried out or done any act with a view to sign or carry out an order purporting to be a reception order or a medical certificate that a person is of unsound mind, and a person who after the passing of this Act presents a petition for any such order, or signs or carries out or does any act with a view to sign or carry out an order purporting to be a reception order, or any report or certificate purporting to be a report or certificate under this Act, or does anything in pursuance of this Act, shall not be liable to any civil or criminal proceedings, whether on the ground of want of jurisdiction or on any other ground, if such person has acted in good faith and with reasonable care.

2. If any proceedings are taken against any person for signing or carrying out or doing any act with a view to sign or carry out any such order, report, or certificate, or presenting any such petition as in the preceding subsection mentioned, or doing anything in pursuance of this Act, such proceedings may, upon summary application to the High Court or a judge thereof, be stayed upon such terms as to costs and otherwise as the court or judge may think fit, if the court or judge is satisfied that there is no reasonable ground for alleging want of good faith or reasonable care.

MANCHESTER HOSPITAL FOR CONSUMPTION.—The formal opening of the new out-patients' department of this institution took place on the 30th ult. The building is situated in Hardman-street, Deansgate, and is erected on a scale calculated to meet the increased work and requirements of the hospital.

Digitized by Google

THE LANCET.

LONDON: SATURDAY, APRIL 9, 1892.

THE appearance of the Registers of the profession—the Register of Medical Students, the Medical Register, and the Dentists' Register—is always an event of much interest to the profession. No medical library can be considered complete without the Medical Register, and the others are very convenient and instructive. We have already given in brief outline the data contained in these official lists, but we always feel moved by them to some reflections on the present position and growth of the profession. It might be thought, with the increasing number and severity of examinations, that the growth of the profession itself would be checked. Of this there is no immediate prospect, if we may judge from the additions both to the Register of Medical Students and to the official record of qualified medical men. Both lists in the present Registers show a marked increase over the preceding year. The addition to the number of students registering is very large, not to say alarming. Thus in 1890 there were registered 1846, but in 1891 no less than 2405. This means not only that 559 more persons were anxious to enter the profession in the latter year than in the former, but exhibits also a number very largely in excess of the increase in any previous year. Indeed, we must go back ten years for the next largest amount of registration of students. In 1881 there were 2171 registrations, but the number last year exceeds the record of ten years since by 234. We have before directed attention to the fact that the increase proceeds irregularly, being more one year and less another. But there has been no such leap in any previous year, and it implies such an excess of any numbers likely to be needed to fill the gaps in the profession that it would be satisfactory to find grounds for regarding it as merely temporary or due to some exceptional circumstance. We have already advanced an explanation. According to a recent recommendation of the General Medical Council, candidates commencing study after Jan. 1st, 1892, must not pass their final examination in medical surgery and midwifery before the close of the fifth year of medical study. In other words, the students on the Medical Register now issued are registered just in time to escape the requirement of a fifth year, and this possibly may have caused the rush. It is somewhat curious to note that the chief increase in registrations of students is in England, where the excess over the previous years is 334. It is next greatest in Ireland (139), and in Scotland it is only 86. Perhaps the prospect of a teaching university in London may have had something to do in determining the large increase in the number of English registrations of students.

Returning to the Medical Register, we may again be excused a word of regret at its (no doubt unavoidable) late appearance, so that a quarter of the year is gone before this official roll is in the hands of the profession or of the Courts. Next we may notice one significant omission from this Register as compared with its predecessors—that of a table, headed in the previous year: "Table G., showing the several Registrable Qualifications, on and after 'the appointed day' (June 30th, 1887), named in the Medical Act (1886), with abbreviations used to denote them in the Medical Register." It is a matter of notoriety that at the last meeting of the Council a little storm was raised over the registrability of the diploma, *per se*, of the Royal College of Physicians of London, and its appearance in this familiar table. The Council by a majority refused to recognise the completeness of this qualification, and instructed its registrar not to register it as such. We have not yet seen the end of this question, the venue of which has been transferred from the Council to the Law Courts, where we may shortly expect an interesting and perhaps costly discussion. Meantime it seems to have been thought that the safest course is to omit the table. In spite of this omission and of the smaller and more compact appearance of the volume, the Register of this year exceeds its predecessor by thirty-six pages. The number of practitioners is larger in this Register than in the last by 392. This addition is less than in the previous year, and less than the average of years. The increase of course fluctuates much, but it is, on an average of ten years, about 618 a year. Last year's Register contained more names than its predecessor by 818. The increase in the present Register would probably have been greater had it not been that the election of direct representatives no doubt caused the removal of many names, such as those of deceased practitioners. The quinquennial election of direct representatives affords a reasonable occasion for comparison of numbers. In 1886 the Register contained 26,452 names; in 1891 it contained 29,555, or an increase in five years of 3103 practitioners.

The removals from the Register are not the least interesting part of the information given in these volumes. Happily there are very few under the penal clauses of the Medical Acts. In the last year they reached five, a number only once previously reached. These, however, are five too many. But the fault does not rest with the Medical Council. Under Clause 14, which empowers the Registrar to remove the names of those of whose existence or residence he has reason to be doubtful, owing to no replies to inquiries being returned, 407 were removed. The number removed on evidence of death, strange to say, does not materially increase. Rather it seems to diminish. For though last year it was 581, as compared with 467 in the previous year, the average has been only 529 in the last five years, compared with 570 in the last fifteen years. It is well known that the Registrar uses every means of getting evidence of the deaths of practitioners, but it is to be feared that many are still unreported to him. Even so it is gratifying to believe that the mortality of the profession is decreasing rather than otherwise. Let us hope that medical men, while increasingly solicitous about the lives of their patients, are also more considerate of their own. The Colonial Register has grown, now comprising ten instead of two names, and all the qualifications are Australian. We cannot leave this volume without testifying to the care with which it seems to have been prepared, and to the value of its tables, Acts of Parliament, and other contents.

Digitized by Google

We have already given the principal facts of the Dentists' Register, and noted the increasing proportion of those whose names are thereon enrolled in virtue of diplomas implying professional education and justifying us in looking annually more and more for professional methods of practice.

WE are in possession of abundance of facts which prove only too clearly that our herds are decimated by a deadly scourge, more damaging by far than contagious pleuro-pneumonia, foot-and-mouth disease, or any other disorder with which we are acquainted; that the milk of the affected animals will readily produce the malady in other creatures consuming these articles; that the disease is highly contagious between individuals of the bovine species; and that the inference is exceedingly strong that human beings are exposed to great danger by the existence of such a disorder among cattle. That the disease is very infectious in the bovine species has been well known to veterinarians for at least a century; that it is readily transmissible, experimentally, by inoculation and by ingestion of the products of diseased beasts has been clearly demonstrated hundreds of times since VILLEMIN published his researches a quarter of a century ago; that it can be communicated accidentally not only to bovines, but to animals of various species, has been shown in the records of numerous cases in medical and veterinary works and periodicals; and that it may be transmitted from animals to man there are several instances to prove. Unfortunately, we cannot experimentally demonstrate that mankind can take tuberculosis from cattle by eating the flesh, drinking the milk, or partaking of the cheese or butter derived from stricken animals, unless it were permissible and right to test the matter on persons condemned to be executed; but there is clinical and experimental evidence to offer that such transmission is possible—nay, highly probable; and there is only too much reason to apprehend that infants and young people incur serious risks from being allowed to consume the milk of cattle which are tuberculous. All this is well known, and for practical purposes is sufficient to warrant steps being taken to grapple with a plague that is terribly common among our live stock, is increasing yearly, and bids fair to destroy it eventually unless vigorous measures are instituted. Surely this alone should long ago have led to sanitary measures being devised and enforced; for though human life is, legislatively, held to be of less value than that of animals, the grave losses inflicted by the presence of bovine tuberculosis in our dairies and in our choice breeds of cattle ought to be sufficient to arouse attention and instigate the adoption of sanitary police measures to limit its ravages. Of the wide and serious prevalence of the malady in cattle there can be no doubt. Perhaps if human health and life had not been at stake the scourge would have been taken in hand long ago; otherwise why should contagious pleuro-pneumonia and foot-and-mouth disease, which are not nearly so destructive or prevalent, be so demonstratively and resolutely dealt with?

It is a mistake to suppose that the existence of tuberculosis cannot be diagnosed in cattle. Every experienced veterinary surgeon can tell at a glance animals which are badly affected—indeed, butchers and dairymen know them well, and indicate them by familiar names. There may be cases which are obscure, but these are comparatively few, we presume, and are not nearly so perilous for the public safety as the cases of those animals known as "piners" or "wasters," or whose udders are involved. Besides, in doubtful cases the veterinary surgeon has his clinical thermometer, and can also have recourse to the tuberculin test, which the highest authorities assert is of positive value as an aid in diagnosis.

With the evidence before us, we must express the opinion, and strongly, that the time has long since arrived when something should be done to stay the course of a disorder that seriously damages property and is a source of great danger to the public health. The malady is not even recognised in the Contagious Diseases (Animals) Act. It is something more than disgraceful that such a pest should be allowed to revel among and destroy our cattle unhindered and unchecked, and that the flesh and milk of these creatures should be dealt out as food without warning and without restriction. With a cause of damage and disease—human and animal—so palpable everywhere, we cannot consider ourselves a very enlightened or humane people if we longer allow it to continue its operations when the steps to be adopted are so apparent and so simple.

THE loose writing and looser thinking characteristic of so much of our popular literature have been well exposed in Professor MASSON'S "Story of Gifford and Keats," in the April number of the *Nineteenth Century*. For nearly seventy years it has been accepted as true in fact that the author of "Endymion" was brought to a premature grave by a severe article in the *Quarterly*, attributed (without authority, it would seem) to its editor, Dr. WILLIAM GIFFORD. The creator of this myth was the young poet's friend, SHELLEY—himself the object of adverse criticism in the same journal,—according to whom the article in question "produced the most violent effect on his susceptible mind; the agitation thus originated ended in a rupture of a blood-vessel in the lungs, and a rapid consumption ensued." SHELLEY, we need not say, was quite without scientific training or scientific faculty; but had he possessed even the scanty initiation enjoyed by KEATS himself in medical study, he would have paused before thus lightly improvising and publishing a more than questionable account of the cause of his friend's death. He asks us to believe that the sense of wrong aroused in KEATS by a scornful depreciation of his first essay in poetry originated a mental "agitation" which "ended in a rupture of a bloodvessel in the lungs," of which the sequela was "a rapid consumption." What medical undergraduate would accept this as a rational or probable history of a pulmonary hæmorrhage? or, even admitting it to be such, would see in the said hæmorrhage the immediate cause of a "rapid consumption?" Phthisis ab hæmoptoë is so rare, or so imperfectly established, that many pathologists refuse it a place in the classification of disease. The hæmoptysis of phthisis (grave enough as a symptom in the early stage, but seldom if ever fatal) is an indication of pre-existing structural lesion, most commonly of tuberculous deposit; and it is simply an inversion of antecedent and consequent to make a rapid consumption "ensue" upon it. But what in KEATS'S case are the

Digitized by Google

facts? As Professor MASSON shows, he accepted the adverse criticism calmly, like the high-souled fellow he was—without anything of the "agitation" sufficient to cause a pulmonary apoplexy. "Praise or blame," he writes, "has but a momentary effect on the man whose love of beauty in the abstract makes him a severe critic of his own work." Again, phthisis, as Professor MASSON duly notes, was hereditary in the family of KEATS, whose younger brother TOM died of it, after being watched by the poet, sitting by his bedside night and day for months. Furthermore, KEATS went through this trying experience after a tour in the Scottish Highlands had, by the privation and exposure attending it, evolved the latent seeds of the constitutional cachexia, shown by the recurring follicular disease of the pharynx he brought back with him. Yet again, in this ominous condition we find him working at his favourite pursuits with greater ardour and intensity than ever, while suffering from what Lord BEACONSFIELD has called "that ignoble melancholy which arises from pecuniary embarrassment." These and other influences, all of them far more adverse to the phthisically constituted poet than the heavy comedy of his critics, Professor MASSON brings before us, with the object and, let us add, with the effect of destroying for ever the hypothesis of SHELLEY that his friend owed his death to the "canker-worms" of contemporary criticism. "The Story of Gifford and Keats" is of value, far beyond its immediate purpose, as illustrating for us the mythopœic element in literature and as running to earth one of its most characteristic and popularly accepted examples. Other contributors to the *Nineteenth Century* might profit by Professor MASSON'S memoir, notably the amiable and accomplished authoress of a paper on "Vegetable Diet," in which, among other feats of what we have called "ecstatic etiology," we find the consumption of animal food from overdriven and maltreated oxen and sheep gravely suggested as the cause of "the excessive and inexplicable extension of cancer within the last decade!"

Annotations.

"Ne quid nimis."

ROYAL COLLEGE OF PHYSICIANS.

ON Monday next, pursuant to Act of Parliament, the Fellows of the Royal College of Physicians will have to elect a President for the ensuing year. Sir Andrew Clark has so efficiently served the College in the past that there can be little doubt about his re-election. He has thrown himself thoroughly into the work of the College, and his tenure of office has been remarkable both for the variety and importance of the subjects brought under discussion, and for the ability with which, as President, he has mastered the details and aided the decisions of the College. In all probability the meeting on Monday will to a certain extent indicate the possible outcome of future elections; such indications, however, are to be regarded merely as friendly signs of the times. At the present moment the College has assumed a very definite position in relation to sundry important questions which have not yet reached their final stage; hence the re-election of Sir Andrew Clark becomes not merely a kindly recognition of his invaluable services, but also a matter of the highest expediency in the interests of the College.

PUBLICANS AND DRUNKENNESS.

IT would seem that among the agents in preventing the tragedies of drunkenness in this country we are to look to the publicans themselves. One of the judges lately—Mr. Justice Grantham, at the Durham Assizes—in sentencing a pitman for manslaughter of a brother pitman, ordered the publican who had supplied them both with drink to stand in the dock. Thereupon the judge reflected on him severely for giving drink to drunken men, to men whom he harboured in his house on pay-day sometimes from midday till the house closed, and at other times from 5 o'clock till the house closed. Not only had he done it in this unhappy case, but the judge declared it had been his practice, and he feared it was the practice of other publicans, to serve men habitually when they were drunk. Such a warning to publicans ought to be a caution. The judge commended to the justices present the telling-off of a special body of police to go about before closing time, visit the houses, and see that drink was not being served to people already under its influence. This does seem one way of getting something like satisfactory police accounts of the drunkenness that is now altogether unchecked and unreported, and of diminishing the disproportion between the numbers of persons found guilty of offences committed under drink and the number of publicans found guilty of supplying drunken persons with drink. In Pennsylvania there is a law making saloon-keepers responsible in damages for injuries resulting from the sale of liquors to intoxicated persons. A recent decision in the Courts there gave substantial damages to a widow whose husband was unable to guide his steps home, fell into a gutter, contracted pneumonia, and died. The publican was held responsible for the pneumonia.

THE STATE REGULATION OF WORKING HOURS.

THE evidence recently tendered before parliamentary committees appointed to deal with the question of hours of labour leaves no room for doubt that these are at the present time excessive. According to one witness, Mr. J. B. Lakeman, inspector of factories and workshops, the working time of women in the metropolitan districts under his supervision varies from eighty to ninety hours per week, a daily average of about twelve hours; and these, as he pertinently remarks, are very commonly spent amid insanitary conditions. The obvious remedy is, of course, to shorten the daily term of active duty, which constitutes the chief occasion of error and the clue to other associated evils. Another suggestion by the same witness is as simple as it is sensible—namely, the allowance of a definite and sufficient time for two daily meals. It is clear that nothing is more conducive to effective work than comfort and regularity where these are concerned. The great advantage of a really pure atmosphere is hardly to be found in a large city, but the reduction of work hours implies at least a relative reduction in the amount of inhaled impurities due to gas combustion. On every sanitary ground, therefore, we would urge the great importance of the proposed new Act for regulating the hours of female labour in shops. The chief obstacle to this measure, it is well known, does not consist in any implied inconvenience to belated customers or to the course of business, but in the competitive keenness which leads a poorer class of traders to labour and make labour at all unseasonable times. Were a work limit assigned and

Digitized by Google

made compulsory, the great mass of tradesmen would gladly avail themselves of the relief thus afforded, and trade itself would flourish none the less because controlled by the time restrictions imposed by obvious necessity. Some decisive step in this direction is everywhere suggested, in the interest of men as well as women, by the physical signs of over-pressure visible among almost all classes of operatives. Certainly the term proposed, seventy-four hours per week, ought to suffice for all ordinary claims of business. The question of inspection, as we have all along maintained, must form an important feature in any scheme of regulation, and this matter, we are pleased to note, has come under the consideration of the Committee on Shop Hours. Similar in its main purpose, and of equal if not greater public importance with the inquiry above mentioned, is the investigation into the hours of railway servants which is now engaging the attention of another parliamentary committee. It is worth noting that even the assertions of superior officials cannot always exonerate railway companies from the blame so often attributed to them in respect of this matter. In the case of a fireman lately dismissed on one of the Irish lines, the misdemeanour alleged to be attributed to him consisted in his refusal, after working twenty-three hours, to undertake duty for a further term of sixteen hours. The same man was said to have been employed in one week for 117 hours. His case was no doubt exceptional, but it can hardly be accepted as unique. It certainly suggests very strongly the need of legislative regulation, as much for the sake of public safety as of ordinary justice to individual workmen.

MR. HUXLEY AND THE TITLE OF DOCTOR.

MR. HUXLEY, it seems, though M.D. of Breslau and M.B. of the University of London, and the happy possessor of endless doctorates of all sorts, objects to the title of "Dr." Huxley. He can stand being called Professor, but draws the line at "Dr.," which many men seem to value so highly. Mr. Freeman and Matthew Arnold, we are told, objected to be called "Professor." It is all intelligible enough. Great men have a consciousness of something *in* them that supersedes all the aid and adornment that titles can give. "When unadorned, adorned the most." And in this they are a warning, if not an example, to lesser men who attach an excessive importance to the mere embellishments of a name.

FRENCH WORKMEN AND SANITATION.

THE Workmen's Congress of Hygiene, to which we have already alluded, promises to be a great success. Distinguished professors and physicians of Paris have promised assistance. The organisers—the National Committee of the French Labour Party—have secured the handsome hall of L'Union du Commerce et de l'Industrie, in the Rue de Lancry, for every Saturday evening during the next six weeks. Here preparatory lectures will be addressed to the working men who have joined the Congress. The public will be admitted to the gallery on the payment of a small fee. The first lecture will be delivered on Saturday, April 9th, by Dr. Dujardin-Beaumetz, Member of the Council of Hygiene of the Department of the Seine (the Paris district), on Alimentation and the Alimentary Regimen. On April 16th Dr. Armand Gautier, Member of the Institute, Professor of Chemistry at the Paris Faculty of Medicine, will lecture on Food Substances of first necessity, their Character, and their Defects. This is expected to be an extremely interesting lecture, for it is well known that Dr. Gautier holds very strong views in respect to the making of bread, and regards modern methods as being dangerous, wasteful, and extravagant. On April 22nd, Dr. Budin, Professor of the Paris Faculty, will lecture on the Hygiene of the Children of the Working Class, Milk-supply, and Crèches. On April 30th Dr. Dumesnil, Secretary of the Consultative Committee of France, Member of the Commission on Insalubrious Dwellings, will discourse on the Sanitation of the Workman's Home. On May 7th Dr. H. Napias, Member of the Consultative Committee of Hygiene of France, Inspector of Factories, and General Secretary of the Society of Public Medicine and Professional Hygiene, will lecture on the Hygiene of Labour—workshops, factories, offices, and retail shops. Finally, on May 14th, Dr. A. J. Martin, Member of the Consultative Committee of Hygiene of France, Professor of Hygiene, will deliver an address on Preventable Diseases, and how to Prevent them. Almost as instructive and useful as these lectures are the excursions and practical studies which are to be made each Sunday following the lectures. The members of the Congress are to be conducted, for instance, to the Paris Municipal Laboratory, where bread, wine, and other such substances will be analysed in their presence, and they will be shown how adulteration is detected. The sewers will be visited and plumbing apparatus examined—in fact hygiene will be studied theoretically by means of the lectures, practically by excursions and visits which the authorities of the town will facilitate in every way within their power. It is only after these six weeks of preparatory investigation that, towards the end of the month of May, the Congress will hold its sitting. The debates, we have already stated, will be limited exclusively to three phases of hygiene: the workman's food, work, and home. The delegates will, by the preparatory measures we have described, have acquired some knowledge of the technicalities of the subjects they are about to discuss; and it will be interesting to hear what the workmen themselves have to say concerning the questions affecting especially the health of their own class.

SMALL-POX AND ISOLATION IN DEWSBURY.

IT had been hoped that the great difficulties which had been felt by many of the sanitary authorities in the Dewsbury Union during the serious prevalence of small-pox would have led to the early provision of some means of isolation which, quite apart from the question of small-pox, would have been available for infectious diseases generally. Batley, indeed, took the lead in the matter, and the Local Government Board, having held a local inquiry, undertook to favour the formation of a joint hospital district and board, and practically promised the applying authorities to aid in its being assented to by Parliament this session. For this purpose a draft order was, indeed, actually issued. At this stage the town of Dewsbury stepped in, and, having called a meeting of a number of the authorities concerned, has secured their provisional agreement to abandon Batley and to join them in the constitution of a different joint board; and the Dewsbury chairman, who presided, naïvely got over the serious delay which the new action necessitates by telling the delegates that the Local Government Board are so fully engaged with Bills this session that it will be impossible for the present for them to do anything in the matter. In the meantime it is announced in the local press that the small-pox epidemic proceeds with a persistency that is truly alarming in this district, which is identified with the manufacture of heavy woollen goods. Fresh attacks are heard of from Dewsbury, Heckmondwike, Birstal, Ravensthorpe, Thornhill, and Soothill-Upper. Dewsbury had last week no less than forty-four acute cases under isolation, to say nothing of thirty-six convalescents. And whilst this is going on incorrect statements are being made as to the vaccination or otherwise of nurses attacked. Thus a statement has been propagated to the effect that a nurse who has been a sufferer had been recently vaccinated. But on the authority

Digitized by Google

of the secretary to the Dewsbury District and General Infirmary, this is not only denied, but it is stated that this nurse and another official are the only officials who had not been recently vaccinated. This case gives support to the very general impression which has prevailed, to the effect that much good would arise from an independent investigation into the relation of vaccination to an actually existing epidemic of small-pox, such as that which is going on in and about Dewsbury; and we are therefore glad that the members of the Royal Commission on Vaccination have obtained the services of Dr. Sidney Coupland for this purpose. Dr. Coupland, who is an able pathologist as well as a discriminating physician, will bring an unbiased mind to the subject he has undertaken to investigate, and whatever the lessons which his labours may have to teach, they will merit and receive attentive consideration. He is already on the spot, and he purposes to proceed continuously with his inquiry.

A HOSPITAL AT MASSOWAH.

ITALY has great opportunities on the Red Sea littoral, but she lacks the money to turn them to immediate account. One of these is the construction of a sanatorium on the Asmara table-land—a delightfully salubrious hill country, which might be made accessible from Massowah by rail in a couple of hours. But beyond "prospecting" it as summer quarters for her seaport garrison she has taken no steps to utilise the magnificent Asmara site, on which British or American enterprise would have run up an attractive health resort long ago, making it a *succursale* to Massowah, at which passengers to and from the East Indies or the Straits might conveniently break the journey. Italy has, however, made a beginning at Massowah itself, and from the *Eritreo*, the local organ of Italian policy, we learn that she has started a hospital, primarily for the behoof of the settlement, but ultimately to be extended and made available for a larger public. The hospital enjoys the patronage of His Majesty King Humbert, after whom it is called, and whose subvention of 5000 lire (£200) attests his interest in it as more than nominal. There are many reasons why Italy should strengthen her foothold in those parts—the adaptability of her settlers to the climate, as already shown in THE LANCET, giving her an advantage over other European competitors in the opening up of the Dark Continent. More than fifty years ago the Capuchin missionary Massaia did noble work to the west of Abyssinia, and surely his initiative might be followed up over the interval between that point and the Red Sea.

THE THERAPEUTIC EMPLOYMENT OF ANTI-TOXINES.

IN the *Medical News* (New York) of March 19th there is an interesting summary of the efforts that have been made to apply therapeutically, in the management of disease in human beings, the results of recent studies upon the chemical products of bacteria, and the substances obtained from the bodies of patients who had died from the disease which these organisms produce. Most prominent among these studies were the results obtained by Behring and Kitasato in their work upon tetanus. Their investigations are well known. They showed that in certain animals which were susceptible to this disease it was possible to produce a condition of immunity against the inroads of the organism that causes it, and that when immunity was once established, the blood serum of the protected animal possessed the property not only of affording immunity to other susceptible animals, but a more or less curative effect when the disease was already in progress. They also further demonstrated that the blood and serum of animals that had been rendered immune against tetanus possessed the power of rendering inert the bacilli that play the etiological *rôle* in the production of this malady. The practical application of this observation to the therapeutics of tetanus was first made by Tizzoni and Centanni, who isolated fro mthe serum of animals rendered immune the anti-tetanus principle, and Tizzoni claims to have employed it with successful results in the treatment of tetanus in the human being. Schwarz, assistant in the surgical clinic at Padua, also reports the successful treatment of a case of traumatic tetanus in the human being by the use of the tetanus anti-toxine of Tizzoni and Centanni. Another case of recovery after this method of treatment is also reported by Schwarz as having occurred in Toscana under the management of Dr. Pacini, and still another is recorded from the surgical clinic of Professor Nicoladoni in Innsbruck. In a similar line the experiments of the Klemperers in connexion with croupous pneumonia must be looked upon as a triumph of bacteriology, even though they are as yet by no means completed. These observers succeeded not only in rendering susceptible animals immune against the form of septicæmia produced by the organism that is believed to be the cause of croupous pneumonia, but also demonstrated that the serum of these animals had the power of affording both immunity against the disease when injected into other animals and of bringing about a cure when injected into animals in which the disease was already in progress. They then directed their attention to the treatment of the disease by this means in human beings, and found that by the subcutaneous injection of the serum of animals rendered immune, the patients suffering from croupous pneumonia, the results were in the main promising. They demonstrated that while healthy individuals and those suffering from other forms of disease presented no systemic reaction after the injection of the serum, in six cases of pneumonia in which the serum was employed there was a marked fall of temperature and slowing of the pulse within the first twelve hours after it was injected. In four of these cases the temperature fell to normal, but rose again after six hours; in the remaining two it fell to normal, and remained there.

PRACTICE IN SOUTH AMERICA.

AS Argentina has sometimes been described as a sort of El Dorado for medical men on account of the high fees which at times have been undoubtedly charged and obtained from wealthy merchants residing in Buenos Ayres, and as the conditions of practice at present are very far from justifying such a description, a correspondent of a well-known German medical journal has recently endeavoured to warn any of his countrymen who think of emigrating against any very elevated conception of the state of matters medical in that part of the world. No foreign diploma is recognised as entitling to practice; but an examination, both practical and theoretical, must be passed in one of the two universities, and this is conducted in Spanish, so that the first requisite is a residence of several months in the country in order to learn the language. In Buenos Ayres the examination lasts quite a month, and includes mental and children's diseases, ophthalmology, and toxicology. The fee is 350 dollars, paper currency, which at present corresponds to about twenty guineas. In Cordova, the other university, the examination is more simple, but the fees are considerably higher. Leave can be obtained, without passing the examination, to practise in localities where there is no doctor, but this has to be renewed every six months, and is refused if a man with a recognised diploma makes his appearance on the scene. Of the 450,000 inhabitants of Buenos Ayres about one-half are foreigners, 15,000 being Germans, and there are already fourteen German practitioners. Since the revolution and the consequent depreciation of the currency the fees have fallen to about the same

Digitized by Google

as in continental capitals, but the expense of living is far greater. In Monte Video a similar Spanish examination is requisite. In Paraguay there is a simple oral examination. In Brazil the examination may be passed in French, and is not so serious an affair as in Buenos Ayres.

THE DYNAMITE EXPLOSIONS IN PARIS.

THE attempt to blow up some private and public buildings in Paris suggests the inquiry as to what means exist for the succour of the wounded. Fortunately, so far, the number of the wounded is limited, but that is due to accident, and not to the nature of the explosives used. The Paris police are not renowned for their urbanity. The men are recruited from anything but the best sources; they are badly paid, and, when, overworked by any political crisis, are apt to become callous and brutal. The other day, when the explosion took place at the house in the Boulevard Saint Germain, one of the principal contributors to the *Progrès Médical* and the director of the hospital La Pitié were in a café close at hand. They immediately rushed to the spot, explained who they were, offered to telephone for ambulances, and to dress the wounds of such persons as might have been hurt by the explosion. The police, however, without even inquiring whether there were any wounded requiring assistance, roughly pushed these medical men aside and rudely sent them away. On the other hand, the police are themselves incompetent to render assistance to the wounded. Many efforts have been made to give instruction to police officers similar to that imparted by the St. John Ambulance Association in England. For some reason as yet not satisfactorily explained these offers have not found favour in the eyes of the authorities. It is said "it is an evil wind that blows no one any good." The anarchist plots will have one not unsatisfactory result if, as is probable, they lead to the better instruction of the police in respect of the care necessary for the succour and removal of the wounded. It is now very generally felt that a larger number to police is required in Paris, that the men must be more carefully recruited, and that it would be a great advantage if at least some among them were trained in ambulance work.

DEATH UNDER CHLOROFORM.

A DEATH occurred on Wednesday, March 23rd, in the practice of a London hospital surgeon, the chloroform having been administered by an anæsthetist of great experience and skill. We have frequently pointed out that these occurrences, sad as they are, must in the present day be to a certain extent inevitable, and will happen even in the hands of the most skilled. It would be as unreasonable to raise the panic cry about chloroform as to refuse to permit any surgical operation to be performed or medical treatment to be adopted because a percentage of deaths is associated with such proceedings. On the other hand, we safeguard our patients by using every precaution against mishap in medicine and surgery, and we draw largely upon the stores of our past experience in deciding whether or not any given operation should be performed in any given case. So should it be with our anæsthetics. It certainly appeals to the sense of the fitness of things that only those who have an extensive experience in the use of anæsthetics should be entrusted with their use, and that each case should be as thoroughly studied from the point of view of the person giving the anæsthetic as from that of the surgeon. The expert has several problems to work out in dealing with any case: he must decide whether an anæsthetic can be taken, what anæsthetic is best suited to the exigencies of the patient, the surgeon, and the operation, and then he has to conduct the anæsthesia in the best and safest possible manner, having in view not only the welfare of the patient, but also the requirements of the proposed surgical manipulation. In the case the particulars of which we have to chronicle below everything was done which could have been prompted by human forethought. The patient, a boy of six, deformed, and somewhat delicate, was chloroformed by an expert with his usual care, and the operation of staphyloraphy was successfully performed. The head was placed in the fully extended posture. The breathing became indistinct just as the operation was completed and the heart failed. Artificial respiration, performed for an hour, failed to resuscitate the boy. The child had successfully gone through several operations before this one. The necropsy, beyond revealing a somewhat small and flabby heart, gave no clue to the cause of death. Although Mr. Warrington Haward and Mr. Pollock, when they urged the value of ether before the Medico-Chirurgical Society, spoke in approval of ether in cleft palate operations, yet the general consensus of opinion on the part of the profession has for years been to favour the employment of chloroform for staphyloraphy as being much more convenient and less likely to interfere with its accurate performance. We must feel deep regret for the death and sympathy with all concerned, but there certainly seems the consolation of knowing that the fatality was, humanly speaking, unavoidable.

"ADDING A NEW TERROR TO DEATH."

IT is not often we find ourselves in some accord with Miss Frances Power Cobbe. But for once we have that pleasure. She has published a leaflet headed "Adding a New Terror to Death," in which she describes and denounces the too common practice of advertising the symptoms of the illness and sometimes the details of the treatment of any patient whose position in the social or political system is at all important. She says that "death-beds are desecrated that doctors may be advertised." There is perhaps a dash of her own animus against the profession in this sentence, but she undoubtedly has hit on a tendency which requires repression. The medical profession is essentially a quiet one, dealing with private and personal facts, the divulgence of which is unseemly. Even in the case where the most important lives are at stake the medical facts are the affair of the patient and his family alone. This is now much better understood than it was a few years ago, but there is enough truth in the satire of Miss Cobbe to justify our giving it this notice.

THE MICROBE AMONGST THE BATAKS.

ALTHOUGH it has long been accepted that there is nothing new under the sun, we usually look for our anticipators in China, where we are specially referred to Confucius. In the *Asiatic Quarterly Review* for January, however, we are referred by "L. B." to M. J. Claine's description of a Sumatra manuscript on the Microbe. Most of these manuscripts are composed of the inner bark of a certain tree cut into long slips and folded in sections. According to Mr. W. Marsden, F.R.S., who writes in 1811, "their contents are little known to us. The writing of most of those in my possession is mixed with uncouth representations of scolopendra and other noxious animals, and frequent diagrams, which imply their being works of astrology and divination." M. Claine has been fortunate enough to obtain one of these manuscripts containing an account of some plague, and from the drawings given he maintains "that the Batak physicians, two centuries ago, had anticipated the modern theory of germs and bacilli." It is interesting to note that this would be shortly after the earliest observations on this subject had been made in Germany, and especially in Holland,

Digitized by Google

by Kircher, Lange, and Leeuwenhoek. The Bataks were an educated people, many of them being able to read and write, and although they probably obtained much of their information from the Hindoos who ascribe diseases to a Kira or worm, it is quite probable that their ideas on the subject of microbes may have been derived from other quarters. In the next number of this quarterly we are promised a translation of some of this Batak manuscript. The illustration produced in the number before us shows a series of lines, spirals, and circles which may be interpreted to represent bacilli, micrococci, and spirilla, leptothrix forms, and the rest; but along with these, and often, as it were, built up of them, are forms which might be meant to indicate insects &c. We shall look forward with considerable interest to the translation of this manuscript.

RECOGNITION OF POOR-LAW EXTRA MEDICAL WORK.

THE extra work of Poor-law medical officers during the influenza season is little heard of, but can well be imagined. It is gratifying to notice in different parts of the country a disposition on the part of boards of guardians to do their duty to such officers. The *Surrey Advertiser* contains the report of a meeting of the Hambledon board of guardians, at which a proposal to offer a bonus of 15 per cent. on their salaries to the medical officers was discussed, and in the end carried *nem. con.* A reverend gentleman tried hard to wreck the resolution on the ground that he saw no reason for such a proposal. The medical men took the office for better or for worse, and they were there as guardians of the poor, not of the medical officers! This gentleman must not be too hardly censured. He is evidently defective in his sense of the reasonableness of things; as if the guardians were not there to do justice to their medical officers, and as if they could better protect the poor than by properly rewarding the medical officers, who had saved the lives of the poor at the risk of their own. We hope the excellent example of the Hambledon guardians will be followed everywhere.

THE PROGRESS OF SANITATION IN INDIA.

WE are glad to learn from the *Pioneer Mail* of the 17th ult. that a Bill was introduced at a recent meeting of the Provincial Legislative Council for the North-Western Provinces and Oudh, dealing with the construction and maintenance of drainage and sewerage works in municipalities. It is certainly necessary that something should be done in this direction, for it seems to be urgently needed, if we may judge from the report of the sanitary commissioner for 1890. That year was a very unhealthy one in the North-Western Provinces and Oudh. The death-rate was higher than it has been since 1879, when it reached 44·8 per 1000. It equalled 37·27 per 1000 in 1890, when there was a marked prevalence of fevers, the registered number of deaths from which reached an enormous total, and attained a ratio of 28·21 per 1000. Fever is often used in India, no doubt, as a convenient label to apply to a number of febrile diseases other than those of malarial origin. Influenza appears to have prevailed as an epidemic, and added its quota to the fever death-rate of 1890. Cholera and small-pox also prevailed to a great extent. The great increase of rainfall over the average, and the increased price of food—owing to the large export of grain to Europe rather than to any bad harvest—no doubt contributed greatly as general causes to the large sickness and mortality. But the drainage, water-supply, and conservancy arrangements are, generally speaking, in an extremely unsatisfactory condition. The present Bill originated with the case of Benares, which was the first of the kind for practical treatment in these provinces. The provision of good water is the great need, but drainage and sewerage are urgently required. The Bill is a general measure, capable of being adapted to different towns with differing and sometimes widely varying conditions. It is largely based on the provisions of the Bombay Municipal Act. The nine chapters of the Bill deal with definitions, with the construction of drainage and sewerage works, the drainage of premises, the enforcement of privy accommodation, the levy of a sewerage rate, and the provision of by-laws, &c. The Bill has, we are assured, been very carefully drawn, in view of the admitted needs of certain municipalities in these provinces, and is believed to offer a fair and sufficient basis for preliminary discussion.

LEUCOCYTOSIS IN PNEUMONIA.

DR R. VON JAKSCH, in the *Centralbl. für Klin. Med.*, draws attention to the fact that the prognosis in cases of croupous pneumonia in which leucocytosis does not appear is very unfavourable. He thinks that in these instances it would be advisable to give by the mouth or hypodermically either pilocarpine, antipyrine, or nuclein, all of which, according to Horbaczewski, increase the number of white blood-corpuscles. Dr. von Jaksch is fully convinced that pilocarpine in croupous pneumonia actually increases the number of white corpuscles when a condition of leucocytosis already exists. For instance, in a patient suffering from pneumonia of the right base the number of white corpuscles was increased 62·7 per cent. an hour after the hypodermic injection of 0·005 milligramme of hydrochlorate of pilocarpine. This sudden increase was not due to the ingestion of food, as the patient during the time was kept without nourishment.

THE ISLINGTON MEDICAL OFFICERSHIP OF HEALTH.

IT is gratifying to know that the responsibility of the action of the Islington Vestry in disregarding its own by-law, and making an appointment to the officership of health without even advertising the vacancy, is left with the vestry alone. The procedure is denounced on all hands. The leading Islington papers declare it to be without justification and without precedent. We understand, too, that a dignified protest has been forwarded to the vestry, signed by most of the leading practitioners in Islington. One of the members of that body, Mr. Elliott, seemed to think that he made a sufficient answer to this protest by saying that the appointment would be advertised, and that the gentlemen who had signed it could all become candidates if they chose. He might have known that none of the signatories are likely to care to become candidates, and that all are entitled to the credit of having no selfish motive in taking the course they did.

THE ETHICS OF CHASTISEMENT.

IN the trial at Dublin of Mrs. Montagu, which has closed with her deserved conviction, the lenity of the sentence inflicted is clearly attributable to the fact that in the opinion of the jury this case was one of tyrannical cruelty in which death was accidental. A verdict of murder would probably have been under the circumstances too severe. As regards cruelty there could be no question, and we have here unhappily a fresh illustration of the fact already well proved by experience, that position and education afford no sufficient guarantees for moral goodness. The inner nature, in spite of these external influences, may remain hard and passionate, and the chastisements which have their origin there will be like in character. The ethics of punishment were clearly and briefly summarised by the Solicitor-General in his speech on this occasion, as allowing a "right of giving chastisement [to children] for their moral culture

Digitized by Google

but the exercise of it must be reasonable, having regard to the age and health of the child." This will be generally accepted as a fair statement of the matter. A parent's will, fancy, or feeling has little to do with it, and indeed severity should not be entirely shunned, if only it be exercised with reason. It is the moral culture which gives to the whole system its keynote. For its fittest and most fruitful method we must rely upon educative more than upon punitive measures. An understanding of the highest moral rule, quite apart from mere maxims of expediency, with a zeal for improving the character, inspired and guided by the great moderating force of love involved, or if this be lacking, as occasionally happens, a sense of duty, instructed by dispassionate wisdom, furnish us with the means of truest success. Thus viewing the matter we recognise a reason for patience, and may fairly hope that the exhibition of its power in trial will prove attractive to those we teach, and will justify and impress on their minds the occasional use of measured and resolute chastisement.

SIR GEORGE BUCHANAN, F.R.S.

WE are gratified to announce that Her Majesty has been pleased to confer the honour of knighthood upon Dr. George Buchanan, on his retirement from the post of Medical Officer to the Local Government Board. A very general desire has been expressed by many who have taken a prominent part and exhibited keen interest in the advance of public health and preventive medicine in this country to mark their sense of the distinguished services which Sir George Buchanan has rendered for so long a period in the health department of the State, and at the same time to show their sense of the loss which his resignation of his official post will entail. The result is that a preliminary meeting has been held, under Dr. Bristowe's auspices, with a view of presenting to Sir George Buchanan some permanent memento of the esteem and regard in which he and his work are held. Sir Henry Acland, who has expressed great personal interest in the matter, will act as chairman of a general committee which will shortly be formed for the purpose. As yet only a small provisional committee has been formed. Together with Sir Henry Acland, K.C.B., and Dr. Bristowe, F.R.S., medical officer of health for Camberwell, the movement is being forwarded by Sir Anthony Home, K.C.B., V.C., M.D.; Dr. Tatham, medical officer of health of Manchester; Dr. Whitelegge, medical officer of health to the West Riding County Council; Dr. MacCabe, of the Local Government Board of Ireland; Dr. W. H. Hamer, of the health department of the London County Council, who will act as metropolitan honorary secretary; and Dr. Thresh, medical officer of health for districts in Essex, who will act as provincial honorary secretary. Dr. Thorne Thorne, F.R S., of the Local Government Board, has also expressed his desire to serve on the general committee.

METHYLENE BLUE IN MALARIA.

A SHORT time since Guttmann and Ehrlich suggested the use of methylene blue in the treatment of malaria. Thayer has since treated five cases in this manner, and his results are published in the Johns Hopkins Hospital Bulletin, vol. iii., No. 19. The dose administered was one grain and a half five times a day. In all the cases the urine was carefully examined, but at no time was albumen found. In all of the cases in which methylene blue was given alone slight strangury followed within the first three days, which, however, was immediately relieved by nutmeg, and in the cases in which nutmeg was given at the commencement of the treatment there were no unpleasant results. The urine in all the cases assumed a deep blue colour; the fæces, although appearing as usual when passed, became blue on exposure to the air. With one exception all the cases were of the more chronic and severe types of malarial fever, those in which the hyaline intra-cellular bodies and crescents have been found in the blood. It is in such cases that quinine is often very slow in its action, and that, even when quinine and arsenic are given together, organisms may be found in the blood for weeks and months. One case of tertian ague yielded almost immediately to the methylene blue, the organisms disappearing on the third day. In another case the organisms had not entirely disappeared in twenty-three days. This was a severe chronic case. In a third case, which appears to have been one of the more severe varieties, no organisms were seen after the ninth or tenth day. In none of the cases was there any chill later than twenty-four hours after the beginning of the administration of the drug. Thayer concludes that methylene blue has certainly a distinct anti-malarial action, a fact which is of great interest, and this treatment is certainly worthy of more extended trial.

DISEASED TINNED MEAT: A CAUTION.

A RECENT conviction in the Liverpool Police-court awakens once more the uneasy suspicion which is apt to be associated, not always unreasonably, with the system of contract supply. It is not difficult to understand the reducing influence exercised on a margin of profit by the lowest cost estimate, and the consequent opportunities of temptation. We may trace these and their effects in every branch of trade, and nowhere more than in the food market. This brings us to the case in question, that of a provision dealer, who seems to have done a large business in tinned meat at the rate of 1½*d.* a pound. A trifling charge indeed, but dear for that which was provided, since we are informed that the contents of 600 tins were found on examination to be "blown" and stinking. The fraud was, in any case, as disgraceful as it could well be. It is satisfactory to know that the heavy fine inflicted on the delinquent dealer must have absorbed considerably more than the slender profits of his dishonest merchandise. The incident is further noteworthy as illustrating once more the truthful force of the rule which bids the buyer beware of imposture—a caution which is in no connexion more needful or more often disregarded than in the purchase of cheap food.

ASSIMILATION OF FAT.

SEVERAL recent Russian graduation dissertations deal with the various conditions which affect the assimilation of fat. Dr. Zvyagintseff has examined the relative assimilation of fat in children fed with fresh and sterilised milk. There does not appear to be any difference, and the amount assimilated during the first three days of a six days' experiment did not differ from that assimilated during the latter three days. He finds that it requires from 90 to 105 minutes to sterilise milk efficiently in a Koch's apparatus; and he is disposed to think that if bottle-fed children were always fed with sterilised milk they would be much more healthy than they are, and their mortality would be greatly diminished. Dr. Bélorusoff finds that warm abdominal compresses diminish the assimilation of fat in healthy subjects, more especially in those who have a good store of fat in the form of subcutaneous adipose tissue, their effects being, on the other hand, less marked in thin subjects. Dr. Popoff administered to a number of healthy persons—students and others—warm baths at 35° C., containing various aromatic herbs, such as rosemary, mint, lavender, &c., and lasting half an hour, for the purpose of determining the alteration produced, if any, in their capacity for assimilating fat. The result was that there was always some increase in the percentage absorbed, the minimum increase being 1·5 and the maximum 6 per cent.

Digitized by Google

Dr. Shimanski found that warm baths containing oleum pini Sylvestris nearly always increased the fat assimilation, the effect being to some extent prolonged for some few days. Dr. Sprenzhin finds that hot-air baths very slightly increase the assimilation of fat, but when the baths have been stopped there is no appreciable after-effect.

PROFESSOR POLITZER IN LONDON.

PROFESSOR POLITZER of Vienna, being on a visit of a few days to London, Sir William Dalby invited all the aural surgeons attached to the general hospitals in London, as well as many others, to meet him on Monday, April 4th. As all the invitations were accepted, there was a large and representative meeting. Sir William Dalby introduced the distinguished visitor, who gave a highly interesting demonstration of preparations and dissections illustrating the normal and pathological anatomy of the ear. The delicacy of some of the specimens, especially those of the membranous labyrinth prepared by Professor Politzer's own hands from the non-decalcified petrous bone, excited the greatest admiration. Some celloidin and paraffin preparations, which were much more easy to make, were none the less extremely instructive. The temporal bones from fatal cases of mastoiditis following influenza, and from cases of deafness in old persons caused by ankylosis (generally fibrous) of the stapes, aroused considerable interest. Professor Politzer then exhibited a number of his recent additions to the aurist's armamentarium, notably instruments for insufflation and injection into the tympanic "attic," and a strong kind of punch forceps for chipping away the outer wall of that cavity. He referred feelingly to the fact that it was in the very room in which this meeting was held that he received his first enlightenment in otology from the late Mr. Toynbee, and expressed himself as being very much gratified by the reception which he had received.

EPILEPSY AND HEAD INJURY.

AFTER a careful review of the whole subject of the relation of epilepsy to head injury Dr. Putnam of Boston concludes that we need not hope in all cases of injury to prevent convulsions by early trephining and care bestowed upon the wound, and he points out that the local and general injury of the brain are probably of the highest importance in those cases, and quite independent of fracture. He regards of great importance the general treatment of the brain by means of cold applications and prolonged absolute mental rest. As to the cause of the convulsions which occur after injury, he thinks it necessary to seek for some further explanation than mere local irritation, especially in view of the fact that a considerable interval so frequently elapses between the accident and the first convulsion, and he suggests as the cause of the convulsions a degenerative process which increases gradually in extent and probably in intensity. He throws out the suggestion that trephining, for the sake of exploring the condition of parts, may possibly be desirable in the case of patients presenting themselves for the first time after the injury, but before the outbreak of the convulsions, in order to make sure that there is no local condition present which may give rise to irritation or may be the starting-point of degenerative processes.

NEW METHOD OF HARDENING BRAIN TISSUE.

IN a recent number of the *Neurolog. Centralbl.* Professor Stieda of Königsberg gives a short description of a method of hardening the brain which had already been described by him in an anatomical journal. By this method dry preparations are obtained which are extremely useful for purposes of demonstration and study. The specimen is first immersed in a concentrated watery solution of chloride of zinc, so much of the salt being taken as to allow the brain to float. After being twenty-four hours in this, the specimen is removed, and is found to have remained soft, but at the same time to have acquired a certain consistence and toughness, so that the pia mater can be removed without injuring the cortex. The brain is now placed in 96 per cent. alcohol, either as a whole or after separation into parts. To expedite the hardening, it is advisable to renew the alcohol from time to time. In two or three weeks the specimen will be found to be sufficiently hardened. It is then taken out of alcohol and placed in turpentine, in which it should remain from two to four weeks, according to the condition of dehydration in which it was previously to being placed in the turpentine. The process can also be hastened a little by using an incubator, but great care is necessary to prevent shrinking. By means of the turpentine the specimen again becomes soft but transparent, and it has acquired a brownish colour varying in tint with the kind of turpentine used. Finally, the specimen is placed in oil varnish, in which it remains for two weeks. It is then taken out and placed uncovered for a week or two, exposed to the usual temperature of a room, until it is dry and no longer oily to the touch. The final colour is a somewhat pleasing brown; the specimen is but little shrunk, and, as has been said, it is very useful for demonstrations and also for study.

DRUNK OR DYING?

WE have taken the trouble to investigate very fully the circumstances which took place at and preceded the inquest, held on the 31st ult., on a patient aged fifty who died in St. Bartholomew's Hospital from apoplexy. Some of our contemporaries have made severe, but we think unwarrantable, comments on the proceedings at the inquest and the medical evidence. The jury returned a verdict that "The deceased died from apoplexy caused by excessive alcohol," and did not append any rider to this verdict or comment on the medical evidence. The first time the man was brought to the hospital, soon after midnight on March 26th, a small superficial scalp wound over the external occipital protuberance was dressed. Mr. Baker, the house surgeon, roused him with the battery. He smelt strongly of drink. The man gave his name and walked away with the constable's help. An hour later he was sent back on a stretcher with a message that the inspector could not rouse him. When Mr. Baker tried to use the stomach pump the man struggled with all his limbs so that the police constables had to hold him. The passing of the tube made him vomit between two and three pints of beer only (i.e., nothing but beer), and during the vomiting he sat up. No evidence presented itself that his drunkenness did not account for the symptoms present, and he was sent away again, this time on the stretcher. This was at 2 A.M. At 8 A.M. he was brought back, and then had right hemiplegia and aphasia. He gradually became more comatose, and died thirty-three hours later. He had no symptoms of apoplexy on the first two occasions when he was at the hospital. He was apparently only drunk then, and it is probable that hæmorrhage began in the interval between his second and third arrival. After admission it was found he had albuminous urine of low specific gravity; also that he had in his pocket a casualty paper of the hospital, showing he had been attending for chronic headache and buzzing in the ears. The explanation of the case appears therefore to be that a man who was drunk was rightly treated for the condition due to alcohol, and was admitted when taken to the hos-

Digitized by Google

pital with symptoms giving evidence of the commencement of apoplexy. Mr. Baker has to our knowledge had exceptional experience in the duties of a hospital resident, and his careful examination was supplemented by that of another of the house surgeons when the patient first applied for treatment. No hospital can afford to keep all the drunken men who are brought to it until they have slept off the effects of their debauch on the chance that apoplexy may subsequently occur.

THE INCREASE OF SMALL-POX.

THE occurrence of two or three deaths from small-pox, and the increase of admissions into the Small-pox Hospital, may be but the first droppings of a storm, or they may have no such significance. There are two responsibilities: the responsibility of the authorities to have telegraphic information of cases notified, to isolate the patient, and, if possible, all who have been exposed to the patient's infection; and, finally, to revaccinate all persons in the immediate environment of the patient—friends, nurses, and others. This is the Leicester system, which has been so successful. It is essentially the protection of vaccination, though the authorities are not magnanimous enough to admit it. There is another responsibility—that of the individual for his own protection and that of his family by vaccination and re-vaccination. Small-pox will laugh at all sanitary advantages where they are not backed by this special protection, and no sensible people will trust to mere public provisions which cannot cover the furtive risks of this locomotive age.

POISONING BY HOMATROPINE.

IN the *Medical News* (New York) Dr. Purley relates the particulars of a case in which symptoms of poisoning by atropine developed after the repeated instillation of drops of a 2 per cent. solution of homatropine into the eyes. The patient was a child of seven, who was the subject of hypermetropia. To procure relaxation of accommodation she was ordered to have homatropine solution dropped into her eyes every fifteen minutes for an hour before returning for examination. She came at the appointed time, and while at Dr. Purley's house nothing unusual was observed. The pupils, as was to be expected, were well dilated. On the way home, however, she became restless and excited, the face was flushed, and her mental condition was peculiar. Her ideas, which were very rapidly expressed, became very incoherent and extravagant, and she saw imaginary objects. Her gait became staggering, hallucinations were very marked and accompanied by mild delirium. She was treated by the family doctor, and the following morning was very much better, but it was several days before she had entirely recovered. The case is certainly curious, for Dr. Purley calculates that only about two-fifteenths of a grain could have been instilled, and, considering how small a proportion of this was likely to be absorbed, it was scarcely to be expected that toxic symptoms would have been produced.

FOREIGN UNIVERSITY INTELLIGENCE.

Berlin.—Dr. Thierfelder has been appointed custodian of the Hygienic Museum.

Breslau.—Dr. R. Stern has been recognised as *privat-docent.*

Buda-Pesth.—Dr. Ernest Schwimmer has been appointed Extraordinary Professor of Dermatology.—Dr. Emil Moravsik has been appointed Extraordinary Professor of Forensic Medicine.

Havana.—The right of granting the doctorate being about to be taken away, four medical professorships with the corresponding assistants' posts will be suppressed. A considerable sum will of course be saved, but in a manner which will seriously interfere with the scientific position of the colony.

Jena.—Dr. Rossbach is about to resign the chair of Medicine and to retire from the direction of the Medical Clinic.

Lyons.—M. Poncet, Professor of Operative Medicine, has been transferred, at his own request, to the chair of Clinical Surgery, in succession to M. Tripier, deceased.

Munich.—Dr. Hans Buchner, *privat-docent* in Bacteriology, has been granted the status of Extraordinary Professor.—Dr. Amann, of the gynæcological clinic, has been recognised as *privat-docent.*

Munster (Academy).—A Professorship of the Chemistry of Foods has been established, to which Dr. Koenig has been appointed.

Paris.—M. Gabriel Pouchet has been appointed Professor of Pharmacology, in succession to M. Regnauld, retired.

Strassburg.—Professor Flückiger, Director of the Pharmaceutical Institute, is about to retire.

WE regret to have to announce the death, on the 3rd inst., of Mr. Charles Hawkins, F.R.C.S., in his eightieth year, at his residence in Duke-street, Portland-place, W. Probably he is best known as having edited the autobiography, lectures, and other literary productions of the late Sir Benjamin Brodie. He was a Fellow, and for some time treasurer, of the Medico-Chirurgical Society, and held the appointment of inspector of Schools of Anatomy in London. He was author of the article, "Lithotrity," in "Holmes's System of Surgery."

A SERIOUS outbreak of scarlet fever appears to have broken out in the neighbourhood of Bexley Heath, Kent. Cases to the number of sixty or seventy had on Saturday last been reported to the medical officer of health, on whose recommendation the churches and chapels in the vicinity were closed on Sunday, and the carrying on of the work of the schools of the locality was ordered to be suspended for the present. A strict inquiry into the origin of the epidemic is called for.

DR. EDWARD DAVIES has been appointed by Mr. B. H. Thelwall, coroner, his deputy for the Eastern or Wrexham division of the county of Denbigh. We understand that it is the intention of Mr. J. C. Davies, L.R.C.P.Lond., of Ruabon, to become a candidate for the coronership (likely soon to become vacant) of East Denbighshire.

THE Otological Congress will be held in Florence in September, 1893, under the presidency of Professor Grazzi. The sitting will be held eight days before the meeting of the International Medical Congress, which will, as already announced, take place in Rome next year.

THE list of names for the Committee on the Registration of Midwives is not yet completed. It will be chosen half by the Committee of Selection and half by the House itself. It is not likely to begin its work till after the Easter holidays.

SIR JOSEPH LISTER, BART., has been elected a member of the Royal Institution.

Digitized by Google

ROYAL MEDICAL BENEVOLENT COLLEGE, EPSOM.

Special Verbatim Report of the Twenty-sixth Festival, held April 5th, 1892.

THE biennial festival of the Royal Medical Benevolent College is an occasion which awakens widespread interest in the ranks of the medical profession, and it cannot be disputed that the interest manifested is well deserved; especially is that the case at the present time. Founded about fifty years ago, the school is practically contemporaneous with the Queen's reign, and old enough, therefore, to have seen some revolutionary changes take place in the accepted views of those who form and stamp public opinion in reference to matters educational. Epsom College, however, is now well abreast of the times in the development of its teaching work. Its record of successes and distinctions won at the two great universities may fairly be pronounced a brilliant one, regard being had to the comparatively small number (200) of lads for whom the existing buildings and appliances provide accommodation. But it is not only, not even chiefly, as a school where privileged terms are offered to medical practitioners for the education of their sons that the Epsom institution appeals to the medical profession and the still larger British public. By its constitution it is made not only a place of education for children, but also a place of asylum for a certain number of incapacitated medical men or widows of medical men, who are provided with annuities and lodging in their declining years. To this charity is added a further gift to the children of parents so disabled in the shape of a free education in the case of sons at the Epsom College to the number of fifty foundationers; in the case of daughters to the number of seven foundation scholarships in connexion with the College at the St. Anne's Society. The amount of distress which has thus been alleviated during the present reign is quite incalculable, and if nothing more were now proposed than the rendering more effective the machinery which has accomplished so much already, the managers of the College would be entitled to claim the sympathy and support of all who have at heart the interests which have with such excellent results been entrusted to their care.

But the Council of the College are not left at leisure to mature their labours as they might reasonably desire to do, for it has been found that the work of the two departments—the educational and the asylum,—to which we have already referred, cannot easily or well be carried on exactly upon the existing lines. The success of the school has resulted in an enlarged and growing demand for admission which, with the existing accommodation, the Council are not able to satisfy. It is, moreover, in no way surprising that arrangements devised half a century ago should now be found to be somewhat out of date, and only imperfectly adapted to the requirements of educational work directed by modern views as to its aims and methods. For all these reasons the teaching staff cry out for improved accommodation, and the Council, impressed with the reasonableness of the demand, and charged with the important task of discovering and carrying into effect a way of satisfying it, have fallen back upon a scheme which will, we think, command general approbation. The scheme is a bold one; but boldness in such a case is no defect, for no weak and halting measures could conceivably meet the case. The plan which they have adopted involves the disappearance sooner or later of the pensioners from the College precincts at Epsom, and the provision of such additional allowances as will enable them to provide for themselves elsewhere, in order that the space vacated by them may be added to the existing accommodation of the College, and turned to account for educational purposes. Such a scheme involves, of course, a very considerable outlay of money, and seeing that the institution was at the time when this plan was originated seriously embarrassed by debt, the credit of boldness, no less than of discernment, is due to those who first put it forward. Its success is now, indeed, a matter of time only. The debt which a few years ago overshadowed the institution has been entirely cleared off, and an exceedingly good beginning has been made with the collection of the capital fund necessary to float the scheme. At the last festival when the project was launched the Council had much less reason than at the present

charged with the important task of discovering
ing into effect a way of satisfying it, have fallen
a scheme which will, we think, command general
tion. The scheme is a bold one; but bolde
such a case is no defect, for no weak and halting
could conceivably meet the case. The plan which
have adopted involves the disappearance sooner
of the pensioners from the College precincts
and the provision of such additional allowances
enable them to provide for themselves elsewhere
order that the space vacated by them may be
the existing accommodation of the College, and
to account for educational purposes. Such a
olves, of course, a very considerable outlay of
seeing that the institution was at the time when
was originated seriously embarrassed by debt, incurred
boldness, no less than of discernment, is due to those
mist put it forward. Its success is now, indeed, a
time only. The debt which a few years ago crushed
the institution has been entirely cleared off, and a
ingly good beginning has been made with the
of the capital fund necessary to
at the last festival when the project was
ch less reason than at the

moment to look forward with confidence to an early realisation of their wishes. By way of stimulating the zeal of the friends of the institution the Editors of THE LANCET undertook to subscribe to this object the sum of £1000 upon condition that the entire balance of £49,000 was subscribed within two years. The interval has now passed, and although the condition has not been literally fulfilled a commencement has been made so full of the promise of an early completion of the subscription list to its required proportions that the promisers of this conditional donation have seen their way to abating the stringency of the condition and have already paid over to the treasurer the promised sum. They feel that having thus evinced their own confidence in the assured and speedy success of the task in which the Council is engaged they are entitled to commend it to the warm sympathy and practical support of readers of THE LANCET. It will be seen on reference to Dr. Holman's speech, published in another column, that the sum of about £26,000 is now required to carry out the endowment scheme for the pensioners.

In thus advocating the cause of the Epsom College Extension scheme they are happy to find themselves in the company of men whose association with the undertaking is both an undeniable voucher of its wisdom and an effective pledge of its success. We refer not only to the distinguished medical men who assisted at the meeting on Tuesday last, but also to the genial presence of the Right Hon. David Evans, the Lord Mayor, who not only presided, but performed his presidential duties in a manner which left no doubt upon the minds of his guests as to the sincerity of his expressions of interest in the work which the gathering had been convened to promote. We acknowledge this courtesy to the medical profession none the less warmly because Epsom College does not limit its advantages to the sons of medical men. It was felt, and justly felt, by the founders of the school that no advantage was to be gained by excluding the general public from its precincts. On the contrary, it always has been the desire and the practice of medical men to cultivate good and close relations with their neighbours not of their own profession, and less perhaps than most other people are they exposed to the temptation of converting their professional association into a form of caste. Only in one sense is Epsom College *exclusively a medical school*—namely this, that the privileged terms which the possession of an endowment enables the Council to offer, in a certain number of cases, are open only to medical men. The sons of parents not coming within the definition are admitted to the School upon the terms of payment of a fee amounting to £70 a year. These, therefore, are received on terms which compare advantageously with other schools affording equal social and educational advantages, and no one who has sons there is likely to complain upon this score. The distinct advantage which a medical man enjoys could not of course be extended to the general public without destroying the medical character of the school. In all other respects the institution is one that serves the public exactly as it serves the profession, and it is no small satisfaction to those who at the present moment are advocating its claims to be able in an appeal which is addressed not only to medical men, but also to the general public, to rest their advocacy upon such very substantial grounds of distinctly public merit as Epsom College justly claims.

The twenty-sixth biennial festival in aid of the funds of the Royal Medical Benevolent College, Epsom, was held on the evening of Tuesday last in the Whitehall Room of the Hôtel Métropole. The Lord Mayor (the Right Hon. David Evans) presided. He was accompanied by Mr. Sheriff Foster. On his right sat Sir Andrew Clark, Bart., Sir A. W. Hemming, K.C.M.G., and Mr. Wakley, F.R.C.S., and on his left Sir Richard Quain, Bart., President of the General Medical Council, and Mr. Thomas Bryant, President of the Royal College of Surgeons. Among those who were prevented from attending may be mentioned Lord Derby and Lord Gifford. The company, however, was a large and representative one, numbering considerably over two hundred and fifty persons. The object of the gathering was to assist the Council of the institution to provide funds in aid not only of aged and disabled medical men, but also of the children of those medical men who, from death or misfortune, have been unable to provide for their families. The pensioners who receive annuities of £21 each, with furnished rooms in the College at Epsom, must be legally qualified medical men who have been registered for five years, or the widows of such. They must not be less than sixty years of age at the time of their application for admission, and their yearly income, independent of any allowance by the College, must not exceed £60. It was with a view of aiding the funds, in the first place, of this charitable institution, and also of assisting in collecting the sum of £26,000 to enable the Council to carry out a scheme for permitting the removal of the pensioners from the precincts of the College, and, by giving them increased allowances in lieu of furnished rooms, to enable them to reside in their own part of the country instead of at Epsom, that the biennial festival dinner was held. After the dinner,

The LORD MAYOR rose and said—I give you the health of Her Most Gracious Majesty the Queen, and may God bless her.

The toast was drunk with enthusiasm, and was followed by the singing of the National Anthem.

The LORD MAYOR then proposed the toast of "The Prince and Princess of Wales and the other members of the Royal Family." He said: We cannot refrain from expressing our deep sympathy with their Royal Highnesses in the terrible sorrow they have been passing through. We sincerely hope and trust that the change abroad will benefit them, and that they may return with their grief lessened somewhat by the change of scene and the change of rest.

This toast was also drunk with enthusiasm.

The LORD MAYOR next proposed the toast of "The Army, Navy, and Reserve Forces," which he coupled with the name of Colonel Meyer, who briefly responded.

The LORD MAYOR, in proposing the toast of "Success to the Royal Medical Benevolent College, Epsom," said: Gentlemen,—In the first instance, permit me, please, to express the great indebtedness and the great honour I feel in being asked to preside over this influential gathering to-night. It is perfectly true that the Lord Mayor for the time being is asked to undertake several important and responsible duties, but even the Lord Mayor hesitates when he is asked to preside over the interests of so valuable an institution as this. I myself hesitated, feeling that possibly I should not be able to do sufficient justice to your cause and to your interests. However, the executive of the Council thought otherwise, and to-night I am in possession of the chair. I have expressed my pleasure of presiding as

Digitized by Google

Lord Mayor. There is on this occasion, however, an additional pleasure and interest on my part, for the very simple reason that my residence is within a mile of this college. Scarcely a day goes by that I do not pass it, either riding, or driving, or walking. I am a local man, residing in the locality itself where this institution is placed. And what is it from a local knowledge that I learn and glean with respect to Epsom College? There is nothing so searching as regards an individual as a local knowledge or reference, either for good or for evil. Wherever we are locally placed, and especially in a small village, we soon find out men's virtues and their shortcomings. And what is it that I locally know with respect to Epsom College? That this institution is worthy of its founders, and that to-day it bears the highest reputation in the neighbourhood which surrounds it; and so, I think, it is fitting—at all events, it is not altogether out of place—that as Lord Mayor first of all, and secondly as a local man, living within short distance of the institution, I should preside here to-night. But to me there is an additional interest. It is that the founder, the actual founder of this institution, was a Welshman, and I, needless to say, am a Welshman myself. I come from the county of Glamorgan, and the founder of this institution came from the adjoining county of Cardiganshire. He was but a poor Welsh apothecary. I believe I am speaking in the presence of his son here to-night, but I do not in any way imagine that this reference, even that the term "poor Welsh apothecary," will in any way upset the son's respect for his father. At all events, this Welshman, for a Welshman he was, founded this institution. But for his initiative, we should not have been called here to-night, and all the immense good recorded of this College would have remained unrecorded. For what purpose, then, was it founded? It was founded to provide an asylum and pensions for aged medical men and the widows of medical men in reduced circumstances; and it does not come within the range, unfortunately, of the knowledge of the majority of us that there are practitioners, many of them friends of ours, others known to us, who have become reduced in circumstances, not in the majority of instances through any mistake on their part, but through the sheer force of circumstances. I have myself, when a youth in Wales, watched many hard-working practitioners in the county of Glamorgan; and I have seen many of them—having more especially in my mind one—called out in the middle of the night to saddle his horse, when the rain was pouring down and the wind blowing cold across the mountains, to visit some suffering patients. And attached to that, what? A large fee? No, a very small one, and in all probability an uncollected fee. That is not an overdrawn picture. Though we are speaking now in London, these experiences which I have recounted are not limited to Wales; and there are medical men much nearer, here in the metropolis, of whom very similar tales of devotion might be told. This institution, then, was founded for that object, and in addition that there should be a school open to all classes, but offering special advantages to the sons of medical men, fifty of whom are foundation scholars; and in addition to which, on the pensioners' side, there are fifty pensioners receiving annuities of £21 each. On the question of pensioners there is a slight, and certainly an unfounded, impression abroad that the contemplated scheme for the enlargement of the accommodation at the College would bring with it an amount of injustice to the pensioners. Nothing of the kind is thought of or contemplated. It is not proposed to remove a single pensioner now resident. That would be wrong, unless they consented. But it is proposed that as they die out no more would be admitted. As to compulsion, there is no compulsion, for if the pensioners do not desire to live in the College it is true that they do not get their house accommodation or their clothes. Nothing of any kind could be done by the Council without receiving the approval of Parliament, and that would be a guarantee that it shall be in no sense an unjust arrangement. This College was founded in the year 1851 by the Welshman, John Propert. On the 25th of June, 1855, it was formally opened by H.R.H. the late Prince Consort, who on that occasion was accompanied by the Prince of Wales. What are we asked to do more especially for this institution to-night? No extracts that I can give you from this excellent report can possibly be information to you who are most of you acquainted with the whole surroundings of this College as well as with its ends. But this night is rather an exceptional one, and it brings with it an exceptional appeal. At this dinner we are asked to assist in meeting the annual outlay for the support of fifty pensioners, of fifty foundation scholars, an outlay amounting to between £5000 and £6000 annually. This, needless to say, is a large amount, but appealing as it does to the large hearts of those present, although it may strike one as being somewhat large, no difficulty of any kind will be felt if one and all decide, not only to maintain their annual subscriptions, but to increase them, and to induce others to do the same. Well, now we come to that which I regard as very important—to aid in raising the sum of about £26,000, so that the Council may give the pensioners augmented incomes, and thus dispose of their compulsory residence in Epsom College, and enable them to spend their declining years among their relatives and friends. Well, now, it does strike me that if this could only be accomplished—and it ought not to be impossible—it would be a step in the right direction. You separate, in the first instance, the old from the young. That is a step which will enable that institution to enlarge the sphere of its educational purpose and action, and at the same time bring with it advantages to the pensioners. Is there anything else that I can say? Anything that can be needed at my hands to arouse you to continue and increase your support of this institution? I think not, excepting that the wording of this report with reference to the profession itself, which is so admirably put together that whoever occupied this chair could not possibly do better than read it, for it brings out what should be, and what, I take it, are our feelings and our sympathies for the medical profession, especially to those of them who are in low water and needful of our help and of our assistance. Speaking of the medical man, it says: "He is bound, if he does his duty, and there are few who do not, to hold himself at all times and in all weathers at the disposal of those who may want his help; he attends the poor as well as the rich; he goes to places and houses, unsanitary as well as sanitary; he expends his life in all climates, and at all seasons; with the result that the lives of medical men are shorter than those of men following other professions, and the time within which they can provide for their families is correspondingly shorter." Words beyond what I have uttered are not required from me; I ask you to give, not only your sympathies, but also, to the utmost of your resources, material aid for the furtherance of the object to promote which we have met here to-night. There is nothing to equal the advantage, either in life or in any other movement, of a good start. For the youth we say, "Give the boy a good start." Anything that gives one a start is an impetus of considerable help, and in this movement we have to-night got a very good start, and a start of a practical, substantial, and generous description. You may recollect that the Messrs. Wakley—I take it that the applause is conclusive evidence that the name is not altogether unknown to you—offered the substantial sum of £1000 if the enlargement scheme of £26,000 could be reached. Well, that was somewhat handicapping us largely. The motive was a good one; but when I tell you to-night that the Messrs. Wakley have withdrawn all stipulations with regard to that sum, and that they say: "With a feeling that possibly such a movement on our part may induce others to follow suit, and with the desire that this should be accomplished, and in an unrestricted form, we hand to you and to your list, Mr. President, to-night the sum of £1000." Is not that a good start, and don't you think it will be an inducement to others to follow suit to encourage generous donors, and that before another president occupies this chair the object shall have been accomplished, and that it shall be his privilege to declare that consummation from this chair, and that the sum of £26,000 has been collected; and if that be arrived at, I do venture to say that it will have been largely and instrumentally due to the fact that the Messrs. Wakley so generously gave us this impetus. I have no more to tell you or to say, excepting that it is my earnest anxious desire that this night's proceedings shall be a substantial success. I give you with the greatest possible pleasure, and hope in that success, "Success to the Royal Medical Benevolent College," and to associate with it the name of Dr. Holman, the treasurer. He is a man, in the first instance, well known in the county of Surrey, not very far removed from Epsom College. I am alluding now to Reigate, where, unfortunately for his friends and his

Digitized by Google

patients there, he is about to vacate, and to come to that greater village, London, where no doubt he will bring all his skill and knowledge for the benefit of the greater number. Therefore, not by way of God-speeding him, but as a recognition of their love and devotion to him, for his eminent services, professional and otherwise, in the past, I know that the people of Reigate and the neighbourhood will not permit Dr. Holman to depart without a mark of their esteem in the shape of a most substantial testimonial as to his value and his exertion and his many services in connexion with this our cause, and it gives me the greatest possible pleasure to associate his name with this toast.

Dr. HOLMAN, in reply, said:—My Lord Mayor, Sheriffs, and Gentlemen,—It is very difficult indeed to return thanks adequately for so large a toast as has been committed to my charge by my colleagues at the College and its Council. I have been present now on many occasions when the cause of this particular institution has been pleaded, but I have never, since the late leader of the House of Commons, William Henry Smith, pleaded our cause, ever heard it done better than to-night. We have had the silver eloquence of a Paget, the humorous sallies of Lord Granville, but the potent, quiet, unassuming manner in which every point which we wanted presented to you has been put forward to-night has seldom been surpassed, and the Council have to thank his lordship most heartily for it. It is perfectly true that two years ago, in this room, I started before you a new idea, and which I then had no warrant whatever from my colleagues for bringing before you. But I had taken counsel with myself and with several gentlemen who had worked with John Propert, and I felt that the proposition put before you was sound. My colleagues in the Council are now with me unanimously, and let it be thoroughly understood that the Council are only following out the views of the family of John Propert in going forward in the course that is now proposed. I ask you, each of you, if you were ill and old and worn out, which would you rather do—would you rather be taken, say from the south of England and transported to Durham or Northumberland, or somewhere or other, to receive £21 per annum, with three tons of coal and free rooms, or would you have its equivalent, and live amongst your friends? It is not a question that ought to be asked for a single moment. And let it be understood once for all that the interest of every pensioner who ever comes within the purview of Epsom College will be thoroughly cared for. No one shall be injured, and no Parliament would ever think of making an Act of this description retrospective. I have found, as far as I can inform myself, that the sum of about £26,000, with the addition of the funds we can now command, would enable the Council to capitalise such a sum of money as would make the position of the pensioner absolutely secure. If that is the case, and if we have a rising school—and we have a rising school,—which is earning its own way, its own honour, and which is improving every year, thanks to the head master and his staff, they tell me that this £26,000 is a sufficient sum. In 1885, seven short years ago, this institution was £11,000 in debt, had ill repute and a diminishing school, and now I turn round and tell you, as the treasurer of the institution, that the school is full. We have an improving and an enlarged property, and now we want more accommodation for the scholars. It is a new departure, it is a good departure, and one for which, as such, I will pledge myself never to rest until the £26,000 are realised. Now, it seems to me a very good suggestion (which has been made since I have been in the room this evening) that many a man hardly likes to commit himself to the idea of being a subscriber for an unlimited number of years to this College, but they may or may not have any interest in this particular scheme. Let them subscribe, say, for five years for this particular purpose, and pledge themselves to it, and they will soon enable me to carry it through. One of England's greatest surgeons has promised £20 annually for life in support of this scheme. Another medical man, a great provincial surgeon, tells me: "I am very greatly impressed with the scheme you propose. I now hand you a cheque for a small sum, and I will put a codicil to my will in which I will leave you £1000." That tells me that the profession is waking up to the value of the scheme I have proposed to you, and you must recollect that we are going on improving the school in a way which has never before been done. As we advantage the school in general, so we particularly advantage the individual foundation scholars who are sent to us to take care of. You cannot send these foundationers to a large school without benefiting them greatly. I do implore you to help your Council to carry out this great reform, and every sixpence of money that you will give will be properly laid out. My Lord Mayor, I thank you for the able and eloquent way in which you have pleaded for us.

Sir ANDREW CLARK, rising to propose the health of the Lord Mayor, said: Our happy—and shall I say in anticipation, our successful?—dinner to-night has had the honour of the presidency of the City of London in the person of the Lord Mayor—the great City of London: the representative of the industries, the wealth, the commercial enterprise of this great nation; shall I add, also, the leader as well as the representative of all the benevolent and all the religious enterprises which characterise this age above every age in the record of civilisation? Well, it has to add two other things, I fancy, to make it a perfect great City of London. With its excitements, its opportunities, its influence, its wealth, it has now to make itself the leader of the intellectual enterprise of this great nation. It has to take and make advantage of the circumstances of the moment, and to subscribe half a million of money to found a new University of London—a university which, by its teaching of the highest knowledge, its dissemination of the truest culture, its promotion of research, shall make it the greatest university of the greatest city of the greatest race which the world has ever seen. Whether it will be wise enough to take advantage of the opportunity I do not know, but I know this, that the opportunity is here, and that if it is missed it will never be recovered. It wants two things. This is one. But there is still another thing. I have ventured to say that it is the leader of the benevolent enterprises which characterise this age more than any other age of civilisation, and if it is the leader of such benevolent enterprises it should be the complete leader, and should cover every great circumstance that comes within this conception of the highest duty. It should turn round to the medical profession and say to it: "We know that you are members of a great profession; we know that you give more than any other profession to the public weal, and that you get back the least of any in return; we know what your toil, your self-sacrifice, ay, and even your martyrdoms, have done for us; and we know that now, when you are wanting help for this great institution, the Royal Medical Benevolent College, and in acknowledgment, not in repayment—the work of the medical profession can never be repaid—but in acknowledgment of our indebtedness to you, we pay up the sum that remains unsubscribed. Here are your twenty thousand pounds." These are the two things, my Lord Mayor, that are wanted to make the City the greatest City of the greatest nation of the greatest race in all the world. I must pass from the City to-night to the person who represents the City of London, and I am commanded to propose the toast of his health, and I have no doubt how you will cordially respond to it. He is a Welshman. If John Propert, the poor Welsh apothecary, with his large heart and his childlike nature, were here in bodily presence with us to-night, how he would rejoice, how he would infect us with his enthusiasm, how he would take extra pinches of snuff, and how he would tell us to honour the Welshman and "come down with the money." Well, there is one thing more, the Lord Mayor is a neighbour of our College, and I think there can be no higher compliment capable of being paid to us than that the neighbour who knows the ill-gossip as well as the good reports, can preside here to-night, and give us by his presence a testimony that our College is worth the presidency even of the Lord Mayor of London. You do not require me to tell you how he has presided over us to-night. The treasurer has told us, and he said he had never heard the cause of the charity advocated in a clearer, simpler, truer, and more efficient way than has been done to-night. I agree with him. It is a pity that the Lord Mayor was not a teacher in one of the hospitals in London, for his power of direct, concise, lucid, and forcible explanation would do honour to the most accomplished teacher. On looking at him I am a little surprised myself, he looks so young, he is so genial, broad, and catholic in all his ideas and words, that I really find it difficult to believe that he is the Lord Mayor of London. But he *is* the Lord Mayor of London, and in giving you his health I would only say, long may the City of London have such Lord Mayors to preside over its councils, and long

Digitized by Google

may we have such chairmen to preside over such meetings and set before us in such felicitous and persuasive terms the claims of this great institution to your support. I give you the health of the Lord Mayor of London, and wish him long life and prosperity, and success in the high office to which he has been called.

The LORD MAYOR, in response, said: Sir Andrew Clark and Gentlemen,—To you, Sir Andrew, I owe a debt of gratitude for the manner—and I must say, as far as I am personally concerned, the too flattering manner—in which you have referred to myself; but no word uttered by you was in too high and too great praise of the ancient Corporation of which I have the honour at this moment to be the head. The Lord Mayor of this City of London is never out of place when he presides at a charity meeting, and the Mansion House of to-day is the Mansion House of the past reputation, having its doors—and they are wide—thrown open in the cause of all charities. It is a proud position to occupy, that of Lord Mayor of the most important and most ancient Corporation in the world, and any man would be proud of it if it were only for the cause of charity. It does bring back to any Lord Mayor occupying the position an amount of great regret as well as satisfaction—satisfaction in the great honour it is, and in the knowledge that it is instrumental for so much good; and regret to find that, all-powerful as it is, it even falls short of the requirements which daily reach the chief magistrate in his capacity as the head of the Corporation. But it is impossible to satisfy all; but nevertheless, and fortunately so, it is able to satisfy many, and as long as the Corporation and the Lord Mayor for the time being, as long as that individual associates himself as representing the Corporation with the cause of charity, so long would it retain the support and the confidence of the citizens at large; and when, in addition to charity, it takes under its cloak the cause of education, though that has not been a neglected cause—indeed, you can scarcely point to any great movement of to-day which is not met with the warm support and cordiality of the Corporation of London. I thank you for the kind manner in which you have introduced the toast, and again express to you, one and all, the great satisfaction I feel in filling the proud position to night of presiding over this gathering.

Mr. LAMB, the Secretary, then announced that the contributions had amounted to £2926.

The LORD MAYOR then said that as John Propert's son was present, he would ask him to address the meeting, and to give them the value and benefit of a few remarks from him.

Mr. PROPERT, on rising, said he felt he was completely out of order in addressing the meeting, but this was quite an exceptional evening. They had to-night, owing no doubt to the persuasive eloquence of the Lord Mayor, beaten the record in the matter of subscriptions. He was willing to admit most freely that it was chiefly owing to the eloquent speech of their President, but he could not forget that there were two gentlemen present who had enabled them that evening to beat the record by their very great kindness in giving them, without handicapping them in the least, a sum of money which he could only characterise as handsome. Messrs. Wakley, by their conduct that night, had earned the gratitude of every member of the medical profession, and he (Mr. Propert) could not allow that meeting to separate without expressing his best thanks to them for their most generous conduct.

The LORD MAYOR then called upon Mr. Wakley.

Mr. WAKLEY, on rising, said: My Lord Mayor and Gentlemen,—We really could not help doing it. We have been during the last two years really very much disappointed. I was informed by my friends, and especially by our valued treasurer, that supposing a considerable sum was promised, dependent upon a certain amount being subscribed within a stipulated period, many persons of business instincts would subscribe to secure the larger sum. From the very first moment that this grand and splendid institution was conceived by the late Mr. Propert, his son will tell you that his father was a frequent visitor to THE LANCET Office, and in that same room which we now occupy, this charitable movement was constantly discussed, and its details considered. And here I must allude to an expression of my right honourable friend the Lord Mayor. He referred to the late John Propert as the "poor Welsh apothecary," as he was always pleased to call himself; but it is well to add to that, what that poor apothecary became in London. A gentleman with the largest possible practice, attending to the health of the greatest men of the day, and one of the most successful and charitable practitioners in London; among all charitable objects he valued none so dearly as this institution, which we are called upon to support this evening. There is no man whose memory should be honoured by the profession more than that of our lamented friend, John Propert. Gentlemen, at this late hour I cannot say much. An editor's place is in his work-room; but I should desire to say for my son and myself that we have always done what we could for this College, and you will forgive me for mentioning that we propose to give—as after the last biennial dinner—to Dr. Holman for distribution, another supplement of 25,000 copies of the report of this most successful meeting. I do hope and trust that the next Chairman, whoever he may be, will be able to tell you—though I may not be alive to hear it—that you have obtained the required £26,000, and that the pensioners are home with their friends, with whom they can live and be happy. Frequently, as I have passed Epsom College, I have taken occasion to enter into conversation with one or two of the pensioners, and those to whom I have spoken were all anxious to return and live among their friends. I have a strong feeling on this subject. We all know that even the lower animals have an irresistible instinct when sick or injured to return home to die. Here Mr. Wakley related a very touching anecdote illustrative of this natural tendency among the lower animals in the time of suffering; and, in conclusion, he said: I ask you, gentlemen, to make on behalf of this endowment scheme for the pensioners every effort on your own part, and to use your influence among your friends to obtain this amount during the next two years.

Sir RICHARD QUAIN, President of the General Medical Council, said Mr. Wakley had spoken of himself and his son. He wished to say a few words about his father. A nobler man never lived than the late Mr. Wakley, nor one who did more good work in the cause of the medical profession. He remembered THE LANCET when it only consisted of half a dozen pages, but now it was a volume, and this was owing to the enlightened conduct of the present Editors. He would like to bear his testimony in favour of the father, and to repeat that, in his opinion, a more excellent man never lived. It would be impossible to exaggerate the importance of the work which he had accomplished on behalf of his professional brethren. The late Mr. Wakley was intimately acquainted with Mr. Propert, and assisted him to a very great extent in carrying out his plan. He (Sir R. Quain) did not see the name of the British Medical Association as in any way promoting this very important object which they had in view. He earnestly hoped and trusted that the magnificent income which they had, accumulating as it was year by year, would be voted, some of it at least, to the furthering of this object.

After the banquet the intervals between the toasts were enlivened by some excellent vocal and instrumental music.

THE VENICE CONFERENCE ON THE SANITARY CONTROL OF THE SUEZ CANAL.

OFFICIAL PRIVATE REPORT OF THE FRENCH DELEGATES.

IN spite of a certain reticence on the part of the authorities, to which we have already alluded, we have been enabled to peruse the proof sheets of an official report, prepared for the private information of the French Government, on the debate held by the representatives of the fourteen nationalities who recently met at Venice. More than this, we have secured a copy of the protocol they drew up, embodying the French propositions, and which has been signed by the delegates of twelve out of the fourteen nationalities represented. This protocol we have translated as literally as possible. It constitutes the actual text of the new sanitary law which the immense majority of the European Powers desire to see applied to the ships passing through the Suez Canal. This is a matter of such vast importance, both from a commercial and a sanitary point of view, that it is most necessary to possess the actual text of the proposed rules. Therefore we have translated every word of the protocol, but we must be content with summarising the accompanying report.

In laying the matter before the French Government, the French delegates to the Venice Conference annex the protocol drawn up and signed by the Governments of Great Britain and of Austro-Hungary, which formed the basis of discussion. This protocol related to the modifications of the Sanitary Maritime Council of Egypt, to the medical qualifications of its members and their salaries, to the revision of sanitary rules affecting the Suez Canal, pilgrims, &c., to the passing of ships in quarantine through the canal, to increase of financial resources for sanitary purposes, to the creation of a corps of sanitary guards, &c. The most important point at issue was the passing of infected ships through the canal. The Anglo-Austrian protocol proposed that English ships going to a port in Great Britain should be allowed, even when infected, to pass through the canal in quarantine. Against these proposals, which we have very briefly summarised, Dr. Proust, in the name of the French delegation, delivered a set speech of which we have the text before us. He pointed out that at the Sanitary Conferences held at Paris in 1851 and 1852, at Constantinople in 1866, at Vienna in 1874, and at Rome in 1885, the only question discussed was the protection of Europe against the importation of cholera. The Venice Conference, on the contrary, seemed more concerned to secure the free passage of ships whether they were infected or not. Thus commercial rather than sanitary interests seemed to predominate. The Suez Canal, he urged, was very narrow, and at some points it would be difficult to prevent communications with the shore. Then a certain number of extra firemen are taken at Port Said and Ismalia by ships going to the extreme East. On the return journey these firemen disembark at one or the other of these Egyptian ports. This is very difficult to prevent. It was precisely in this manner that the firemen who landed from the ss. *Timour* introduced the cholera into Egypt in 1884. At least, this was the opinion expressed by the German delegation which was sent under the direction of Dr. Koch to study this epidemic. It was also the opinion of Dr. Mabé, the sanitary authority sent by the Sultan to make a similar investigation. Nor can the right to pass in quarantine be granted to one single Power: the mail ships of that Power would have an unfair advantage when competing against other lines of steamers. But for the other Powers, the distance between their ports and Port Said is much shorter than from the English ports. The danger is therefore greater; also fraud is always possible. Thus, in 1890, a steamship obtained permission to pass through the canal in quarantine, as the captain declared he was going direct to an English port. He, however, stopped on the way, and cast anchor in the harbour of Pauillac One such incident, one case out of a thousand, would suffice to provoke an epidemic in Europe that might last several years, might cause a disastrous mortality, and would bring about the imposition of incoherent and excessive quarantines in Mediterranean, American, and other ports, thus causing far more trouble to the interests of navigation and commerce than the precautions the French delegation proposed. Dr. Proust then described what, in the main, is set forth in the protocol which the Conference ultimately adopted, and which we append to this report. These precautions Dr. Proust defines as, in one word, "affording the greatest possible facilities when a ship has a clean bill of health, or as imposing effective but not vexatious measures against all vessels that are infected or likely to be infected." The most striking argument brought forward is that in which Dr. Proust demonstrates, by quoting statistics, how little these measures would interfere with the traffic in the canal. Thus in 1886 the number of ships passing through the canal amounted to 3100; in 1887 it was 3137; in 1888, 3440; in 1889, 3425; and in 1890, 3389. Of these ships the number which would have come under the category of infected ships, or of "suspects," were, from 1885 to 1891, only two vessels. These two ships passed through the canal in 1886. They were the *Euphrates* and the *Gulf of Mexico*. The one came from Bombay the other from Calcutta. Cases of cholera had occurred on board within six days of their arrival at Suez. One ship had six cases, the other had five. The number of ships that might be qualified as "suspects," and which passed through the canal, was as follows:—13 in 1885, 6 in 1886, 4 in 1887, 8 in 1888, 9 in 1889. Only one in 1890, and 7 in 1891. Thus in the course of seven years there were only fifty ships which would have been stopped at the Wells of Moses for the time necessary to ensure their disinfection. But of these fifty ships there were thirty which passed through the canal in quarantine, so that there remain only twenty which would have been detained for disinfection. We have therefore a total of twenty suspicious ships and two infected ships in the course of seven years. What would be the material effect on the commerce of the world produced by the detention of twenty-two ships out of a total of more than 20,000 ships in the course of seven years? How much greater is the inconvenience and loss likely to be incurred if Europe were exposed to the danger of infection brought to its shores by these twenty-two ships. Dr. Proust added that if better precautions were taken before leaving Eastern ports the number of ships likely to be detained, though already so small, might be still further reduced. For this purpose it would only be necessary to disinfect all dirty linen before taking it on board, or else to disinfect the same during the journey. Dr. Proust warned the Conference of the reaction which would ensue if, through the neglect of prudential measures, cholera once more visited Europe. Quarantine might then be reimposed with more vigour and with results more disastrous than in times gone by.

The speech delivered by Dr. Brouardel, Dean of the Paris Faculty of Medicine, has also been printed for the consideration of the French Government. He insisted that the Anglo-Austrian Protocol did not provide sufficient guarantees against the danger of infection. Science had made great progress since the last Conference. We were now acquainted with the bacilli of cholera. We know that they reside in the dejections of the patient, or in the soiled linen. We know also that the bacillus has a prolonged vitality, that for months it retains its virulence; that at New York, after the lapse of a year, it provoked a new epidemic. He maintained that there were bacilli on board the ships, and simply demanded that they should be destroyed on their arrival at Suez. Our position, he said, was much more favourable than when the previous Sanitary Conference met at Rome in 1885. At that epoch, Dr. Koch had but recently discovered the bacillus of cholera. The matter was still uncertain, but now so many investigations have confirmed the discovery that it is no longer open to question. In 1885 disinfecting stoves were quite a novelty, and their efficacy was still open to doubt. Now they had been in use for several years. Thus the morbid germs and the means of destroying them were known. Why, then, should we not destroy them? Dr. Brouardel proceeded to praise the sanitary measures adopted by the English port authorities, and wished to see similar measures applied at Suez. They might not prove infallible, but, though convicts occasionally escaped from prison, that was no argument in favour of abolishing imprisonment. The precautions proposed for the Suez Canal had already been applied on the Spanish frontier. Each train was stopped and disinfected. There were every day from 300 to 400 passengers and a certain amount of linen to disinfect. The trains were not detained for more than half an hour. The total time required for disinfection at Suez would not exceed seven hours for 300 persons. Then, to avoid even this slight delay, ships might carry their own disinfecting

Digitized by Google

stoves, and in the course of time what occurred on the Spanish frontier towards the close of the cholera epidemic would also happen at Suez—namely, the passengers would be careful on arriving not to have any dirty linen. As for the contaminated ships—and there were only two in the course of five years—a delay of five days was demanded. It is necessary to clean the ships, the soiled cabins, &c., and the passengers may still be in the period of incubation. This period does not seem to exceed three days, and thus, after the third day, the ship might be allowed to pass through the canal in quarantine if there is a disinfecting stove and a doctor on board. Dr. Brouardel, having explained that the expense of such measures would be small, insisted, on the other hand, on the immense losses resulting from cholera epidemics. In 1884-85 Spain lost 180,000 inhabitants through cholera. Intense misery ensued. At Marseilles the loss in money from the epidemic was estimated at 300,000,000 fr., and a certain number of British subjects shared in this loss, thus proving the solidarity of the interests of commerce and of public health. Referring to the suggestion of an English delegate that each nation should do as it chose, he objected that continental countries were not, as England, separated from each other by the sea. Their intercourse was so intimate that they suffered the one for the defects of the other. Then, if infected vessels were allowed to pass through the canal because they were going to England, what would happen in case of shipwreck on the coasts of the Mediterranean. Were we to refuse help when such ships were in distress? In 1873 a French captain made a false declaration on arriving at Havre. He was given free pratique, and an outbreak of cholera ensued. In 1866 a similar case occurred at Constantinople, and cholera again ensued. During the same year the *Sydney*, under analogous circumstances, imported cholera to Suez. Therefore the declaration of a ship's captain does not suffice.

In the discussion which ensued, Dr. Proust reminded the Conference that the English delegates in 1885 wanted the Suez Canal to be treated as if it were an open sea. But this suggestion was almost unanimously disapproved. It found favour only with the representatives of England and of British India, and was rejected by eighteen votes against two. Answering the criticisms made by the Hon. J. W. Lowther, Dr. Proust did not object to being called a scientific theorist. He was convinced that no prophylactic measure could be good if it did not rest on a scientific basis. He could not guarantee that the measures proposed would be infallible, but they would certainly reduce the danger of importing cholera to a minimum. Nor did he think that there would be any great difficulty in isolating passengers at the Wells of Moses. They proposed to build a hospital and infirmary and a disinfecting establishment, and the whole should be surrounded by a wall, to render surveillance more easy. Mr. Lowther had remarked that the presence of a doctor and a stove on board did not prevent an invasion. But Dr. Proust replied that they facilitated the isolation of the sick and the disinfection of soiled objects. Mr. Lowther had said that the surveillance exercised at Suez had not prevented the epidemic at Damas. But this had no connexion with the Suez Canal, for the cholera came from the Persian Gulf. The French delegation in view of this fact, were desirous of introducing, at a later period, a resolution in favour of establishing serious measures of control on the Persian Gulf. Suez is undoubtedly the most important door through which the cholera may reach Europe; but this is not the only door we should watch. In 1823, 1830, and 1846 the cholera penetrated Europe by the land route. Cholera follows human currents. The land route was then the most frequented. It will be necessary later on to watch the Persian Gulf. There it was that horse-dealers, coming from India, spread cholera through Mesopotamia. Mr. Lowther had said that though England was not seeking to acquire any privileges she was anxious to shield Egypt from the risk of infection; but Dr. Proust, to prevent this risk, did not propose to establish a sanitary station at Suez, and the Wells of Moses had been chosen instead, expressly for the purpose of avoiding the risk to which Mr. Lowther alluded. Ataka might have been selected in preference, but this place is on the African coast—touches Egypt,—whilst the Wells of Moses are separated from Egypt by the canal. The risk of infection is further reduced by the fact that this station would serve only for ordinary ships, while the pilgrim ships would be stopped much further away, at the lazaretto of Gebel Tor.

Such were some of the principal arguments adduced by the French delegates at the Venice Conference. Their pleading proved successful; for the protocol ultimately adopted embodied most of their proposals. The following is the translation we have made from the French text of this international treaty:—

TEXT OF THE PROTOCOL SIGNED BY THE REPRESENTATIVES OF ALL THE POWERS EXCEPTING ENGLAND AND TURKEY.

The principle of the passage in quarantine of ships through the Suez Canal, formulated by the Anglo-Austrian protocol, is accepted on condition that the following measures, destined to protect the public health of Egypt and of Europe, shall be applied. For this purpose ships are to be divided into three classes:—1. Ships with a clean bill of health. 2. Suspected ships. 3. Infected ships.

1. *Ships with a clean bill of health.*—Ships which after medical inspection are declared free from contamination shall have immediate free pratique whatever may be their character. They shall not be submitted to the twenty-four hours' observation actually prescribed against ships of a certain category (*patente brute*).

2. *Suspected ships* shall be qualified as such:—Ships having a case of cholera at the moment of their departure or during the journey, but no fresh case of cholera during the previous seven days. Such ships shall be treated in a different manner according to whether they have or have not on board a doctor and a disinfecting apparatus (stove). (*a*) Ships having on board a doctor and an apparatus for disinfection (stove), fulfilling the required conditions, shall be allowed to pass through the Suez Canal in quarantine under regulations to be indicated further on. (*b*) Other suspected ships not having on board either a doctor or a disinfecting apparatus (stove) shall, before being allowed to pass in quarantine, be detained at the Wells of Moses during the time required to disinfect the dirty linen, body linen, and other susceptible objects, and to ensure the sanitary condition of the vessel. If it is a mail steamer or a steamer especially employed for conveying passengers, which has no disinfecting apparatus (stove) but has a medical man on board, and if the local authority has the assurance, resulting from an official examination, that measures of sanitation and disinfection have been properly applied either at the point of departure or during the journey, passage in quarantine through the canal shall be allowed. If it is a mail steamer or a steamer specially employed for the passenger service, not possessing any disinfecting apparatus but having a doctor on board, if the last case of cholera occurred more than fourteen days previously, and if the sanitary condition of the vessel is satisfactory, free pratique may be given at Suez when the disinfecting operations are terminated. For ships that have effected the passage in less than fourteen days, passengers going to Egypt shall be disembarked at the Wells of Moses and isolated during twenty-four hours, and their dirty linen and other articles in use shall be disinfected. They shall then receive free pratique. Rules shall determine under what conditions the dirty linen shall not all be disinfected.[1]

3. *Infected ships*—that is to say, ships having cholera on board and new cases having occurred within the previous seven days. Such ships shall be divided as ships with a doctor and a disinfecting apparatus (stove) and ships without a doctor and disinfecting apparatus (stove). (*a*) Ships without a doctor and without a disinfecting apparatus (stove) shall be stopped at the Wells of Moses; the patients shall be disembarked and isolated in a hospital. Disinfection shall be carried out in the most complete manner. The other passengers shall be disembarked and isolated in groups composed of as few persons as possible, so that all the passengers shall not suffer if the cholera develops itself in one particular group. The dirty linen, all articles in use, the clothes of the crew and the passengers, shall be disinfected, as also the ship itself. It is well understood that there is no question of discharging the cargo; the disinfection is only applied to the part of the ship that has been infected. The passengers shall remain five days at the establishment at the Wells of Moses. When the cases of cholera occurred several days previously, the duration of this period of isolation may be reduced.

[1] When cholera shall attack only the crew of the ship, the linen of the crew only shall be disinfected, but all the linen of the crew must be disinfected, and all the linen belonging to that part of the ship inhabited by the crew.

Digitized by Google

This duration will vary according to the date of the last case of cholera. (*b*) The passage in quarantine may even be granted before the end of the five days by the sanitary authority after the disinfection has been carried out, if the ship has a doctor and disinfecting apparatus (stove) on board which fulfils the required conditions. In respect to mail ships, in cases where the disease has only invaded a limited portion of the ship, the local authority shall judge as to the necessity of landing the passengers, and of the number of persons, according to the places they occupied on board, who should land. The local authority shall also decide what portions of the ship must be disinfected. An exception is to be made in cases of transports conveying a large quantity of troops submitted to military discipline. If the ship has a doctor and a disinfecting apparatus (stove) on board, the sanitary authority may order that only the persons lodging in the compartment where the case of illness has occurred shall be forced to land. While they are disembarking, this compartment, or the section of the hospital to which the patients had been transported, together with all the objects used by the persons who were in personal contact with the patients, shall be completely disinfected. The sanitary authority on board shall declare upon oath which are the suspected or the infected compartments of the ship. The dirty linen belonging to the remainder of the troops shall be disinfected on board. Further, a stove, placed on a hulk, may come alongside the ship so as to help in more rapidly carrying out the disinfecting operations.

RULES CONCERNING THE PASSAGE IN QUARANTINE.

1. The sanitary authority at Suez shall grant the permission to pass in quarantine. The Council shall be immediately informed. In doubtful cases the Council shall decide. 2. A telegram shall at once be sent to the authority appointed by each Power. The ship in question shall bear the cost of the despatch. Each Power will decree penalties against the ships which abandon the course indicated by their captains, and unduly enter the ports belonging to the territory of such Powers. Exception is made in cases of accidents of a compulsory character (*force majeur et de relâche forcée*). 3. When boarded, the captain shall be held under the obligation of declaring whether he has on board indigenous native firemen (Lascars and others) or any other sort of paid servant not inscribed on the log book. 4 An officer and two sanitary guards shall go on board. They must accompany the ship to Port Said. Their mission will be to prevent any communications, and to watch and see that the measures prescribed during the journey through the canal are duly executed. 5. The taking on board or the landing of passengers or of goods during the passage through the canal from Suez to Port Said inclusively is forbidden. 6. Ships going through in quarantine must effect the transit without stopping or stationing on the way. In case of running aground or of other unavoidable accidental stopping the operations necessary must be performed by the persons on board, and all communication with the staff of the Suez Canal Company at Suez must be avoided. 7. The stationing of ships passing in quarantine is forbidden at Port Said. The provisioning of ships must be carried out with the resources on board. Stevedores or other persons who shall have gone on board shall be isolated on the quarantine pontoon; their clothes shall be disinfected according to the rules. 8. When it is indispensable for ships passing in quarantine to take coal on board at Port Said, they must carry out this operation outside the port between the jetties. 9. The pilots, the electricians, the agents of the Company, and the sanitary guards shall be disembarked at Port Said, outside the port, between the jetties, and thence conducted to the quarantine pontoon, where their clothes shall be completely disinfected.

Appended to the protocol adopted by the Venice Conference is a series of regulations, describing the preventive measures that should be taken on board ship at the Dr. Ruysch; Turkey, Dr. Arif Bey, Colonel Bonkowski Bey, and Dr. Haïreddin Bey; Italy, Dr. Pagliani and Dr. Torella.

The instructions drawn up by this committee are headed with the following note:—"The germ of cholera is contained in the digestive organs of the patients, its transmission is effected more especially by the dejections and the matter vomited, and consequently by linen, clothes, and hands that have been soiled."

We now translate the directions given by the International Committee:—

I. *Measures to be taken at the point of departure.*—1. The ship's captain must watch and see that no person suffering from a suspicious choleriform complaint shall come on board. He must refuse to allow on board linen, rags, bedding, and, in general, all articles that appear dirty or likely to be contaminated. Bedding, clothes, rags, &c., having belonged to persons suffering from cholera or from a suspicious malady, must not be brought on board. 2. It is highly desirable that when emigrants or troops are to be transported they should be gathered together in groups and watched for five or six days before they are allowed to go on board, so as to ascertain if any among them are contaminated by cholera. 3. Before going on board, the ship must be thoroughly cleansed and, if necessary, thoroughly disinfected. 4. It is indispensable that the water-supply put on board should be taken from a source absolutely exempt from the danger of contamination. There is no danger if the water has been boiled or distilled.

II. *Measures to be taken during the journey.*—1. It is desirable that in each ship there should be a special place reserved for the isolation of persons suffering from a contagious disease. 2. If this does not exist, the cabin or other place occupied by the person attacked by cholera must be isolated. The persons entrusted with the duty of nursing the patient shall alone be allowed to enter, and they in their turn must be removed from the risk of all contact with other persons. Bedding, linen, clothes, and other objects which have been in contact with the patient and in the cabin occupied by the patient must be plunged into a disinfecting solution. The clothes of the person who nursed the patient must be treated in the same manner if they are soiled. Those objects which have no particular value shall be burnt or thrown overboard if the ship is in the open sea and not in the canal or in a port. The more valuable articles shall be conveyed to the disinfecting stove in air-tight sacks dipped in a mercurial solution. If no disinfecting stove exists on board these articles must remain for two hours immersed in a disinfecting solution. 3. The dejections of the patients (vomit and fæcal matter) shall be received in a vase in which a disinfecting solution, which will be described further on, has been previously placed. These dejections must be immediately thrown into the closets, and the closets must be rigorously disinfected each time that the dejections of cholera patients have been thrown into them. 4. The place occupied by the patient must be rigorously disinfected according to the rules indicated further on. 5. The corpses, previously enveloped in a shroud impregnated with a mercurial solution, shall be thrown into the sea. 6. All the prophylactic operations carried out during the journey shall be inscribed in the log-book, to be shown to the medical authorities on arriving at Suez. 7. These rules are applicable to all who have been in personal contact with the patients.

III. *Measures to be taken on the arrival of a ship at Suez.*—1. All ships must be submitted to medical inspection before entering the canal at Suez. 2. This inspection shall be carried out by the sanitary authority of Suez. 3. If the ship is infected, the persons suffering from cholera or who are thought likely to be contaminated shall be disembarked and isolated in a *locale* specially constructed for this purpose near Suez. Shall be considered as likely to be contaminated: All persons having symptoms of cholera, notably diarrhœa. 4. All contaminated or suspicious objects shall be disinfected before the ship enters the Suez Canal. Shall be

objects: Clothes, bedding, mat-
her articles which have been in
, as also the clothes of those who
the objects contained in the cabin
, in the cabins next to the patient's
ntiguous.

isinfection.—1. The rags, clothes,
of little value shall be destroyed

Digitized by Google

by fire. 2. Linen, bedding, clothes, mattresses, carpets, papers of value, &c., contaminated or likely to be contaminated, shall be disinfected in stoves by steam under pressure. Only those stoves which have been tested with the aid of a maximum thermometer shall be considered as efficacious disinfecting apparatus. This thermometer must prove that, within the centre of a mattress, 105° to 110° C. have been attained. This degree of heat is slightly in excess of that necessary to kill the known pathogenic micro-organisms. To ensure that the operation is efficacious, the temperature must be maintained at this elevation consecutively for from ten to fifteen minutes. 3. Disinfecting solutions:—(*a*) Sublimated solution of 1 per 1000, with 5 grammes of hydrochloric acid added. This solution should be coloured with fuchsine or eosin. It must not be kept in metallic receptacles. (*b*) A 5 per cent. solution of pure carbolic acid crystals. (*c*) Freshly prepared lime: To secure a very active solution, lime of good quality should be selected and mixed gradually with half its weight of water. When the mixture is effected the powder should be put in a carefully closed vessel and kept in a dry place. 4. Special advice with regard to the employment of disinfecting solutions: All linen and clothes soiled by dejections from the patients must be immersed in a sublimated solution. Such objects as may be deteriorated by exposure to the high temperature of the disinfecting stove—objects such as leather, tables, parquetry, flooring, &c. shall be washed with a sublimated solution. The persons who are attending the cholera patients must wash their hands and faces with a sublimated solution of 1 per 2000. Carbolic acid can be employed to disinfect such objects as are injured by a temperature of more than 100° C, or by contact with the mercurial solution, such as metals, instruments, &c. The lime is specially recommended for the disinfection of the dejections of patients, their vomit, and their alvine evacuations. In its absence, carbolic acid can be employed. 5. The cabins or other parts of the ship occupied by cholera patients or persons suffering from suspicious symptoms shall be emptied and the objects they contain submitted to the above treatment. The walls shall be disinfected with the sublimated solution, containing an addition of 10 per cent. of alcohol. The floor shall be washed with the same solution. Two hours later the whole of these surfaces shall be washed with a large quantity of plain water. 6. To disinfect the hold of a ship, and to neutralise the sulphuretted hydrogen, a sufficient quantity of sulphate of iron should be injected into the bilge water. Afterwards it is to be washed out with sea water; then a certain quantity of sublimated solution may be injected. The bilge water must not be emptied into a port.

THE REFORM OF ATHLETICS.

THIS is a subject of present interest, particularly on the Continent, where the systematic training of the bodily powers forms a far more prominent part of education than among ourselves. In France, in Germany, in Sweden, and in Italy something like an international discussion has for some time been devoted to it—the contribution of the last-named country being especially valuable from the scientific ability of its representative, Professor Angelo Mosso, of Turin. That eminent physiologist, whose doctrine as to the pathology of fatigue is familiar to readers of THE LANCET, attacks the gymnastic system traditional in Italian schools, and in a recent paper in the *Nuova Antologia* insists, as a first step in his argument, on the capital distinction between "robustezza" (robustness) and "forza" (strength). The former, he maintains, is often developed out of proportion to the bodily health, as, in order to ensure an abnormal power of muscle, the other organs are, *pro tanto*, impoverished.

As a consequence modern gymnastics (and not in Italy alone) are open, in physiological eyes, to grave objection. Repeated exercise, he admits, augments muscular force—the muscular tissue itself becoming thickened and the organism habituating itself to the products ("poisonous" as these are) of muscular waste. But, as is well known, during intense strain or extraordinary effort the blood no longer circulates healthily, the respiration is altered, the pulsations of the heart are irregular. The artificially widened thorax, on which the athletic enthusiast so prides himself, is, according to Professor Mosso, of a highly relative value, for even without such widening we always respire a sufficient quantity of air, and even habitually, as he further maintains (in a special monograph) "we respire more air than is necessary." The gymnastics of the schools have this defect, that they "localise fatigue in some groups of muscles," whereas really healthy exercises should induce a fatigue of the whole body—a symmetrical fatigue—and that gradually. Recent experiments on the results of fatigue of the muscle have shown that that tissue suffers more (pathologically considered) from a maximum than from an ordinary contraction; and, besides, that to the weary muscle a given effort is more hurtful than to the muscle which has rested.

Professor Mosso gives an instructive sketch of the phases through which gymnastics, from the beginning of the nineteenth century to its close, have passed in the schools of Italy. Received at first with enthusiasm, this new adjunct to education became very soon stationary "on account of its military character." Between the two chief gymnastic systems, the Swedish and the German, there was a struggle for popular favour, the former being the more "intense," the latter more gradual, and basing itself on physiological science as then known. Even by the Swedish method, according to Professor Mosso, "the development of the muscles and the 'allenamento' (power of keeping in the breath) are obtained less rapidly than on the traditional Italian system, but its results are more hygienic and more assured." It is, he reminds us incidentally, from the Swedish gymnastics that the so-called "ginnastica chirurgica" and massage took their rise.

Several commissions have, in Italy, undertaken to revise the contending gymnastic systems, and to make salutary innovations accordingly. But Professor Mosso has little confidence in the finality of these. He rather points to France, where, as a means of fortifying future generations, an effort is being made to give gymnastics a soundly scientific direction,—an effort in which the physiologist and the education authorities are coöperating loyally. The first step taken by these reformers was to assimilate from abroad whatever seemed useful and practical, and next to compile a manual of gymnastic exercises, commendable, according to Professor Mosso, for its clear intelligible character and for the cheapness which makes it accessible to all. France, he tells us, has a military school of gymnastics where instructors are prepared for other schools; and he sounds a warning note to Italy, where no corresponding institution exists, to take a leaf out of the French book betimes, while within measurable distance of war, with its rapid mobilisation, and with the energetic movements characteristic of modern strategy. "It is but too true that in Italy politics are all-absorbing, and her legislators think the problem of physical education beneath them." The meagre endowment of her physiological laboratories is fatal to the furtherance of such education—a fact all the more to be lamented when Italy teems with men able to give her a pre-eminence in gymnastics as notable as she has long held in other departments—that of fencing and sword exercise, for example.

At present athletic or gymnastic discipline is not in favour with Italian youth, those schools in which it is practised always numbering many truants from its classes; while the "theory" of such discipline gets more and more involved in unpractical pedantries, irksome to the youth, and embarrassing to the instructor, and erroneous ideas as to the efficacy of certain "intense" forms of exercise come in as a further complication. There is, moreover, the traditional prejudice that during muscular exercise the brain is at rest—a position, according to Professor Mosso, "absolutely false." When the distinguished Hellenist, Professor Sellar made his first appearance on the golfing green at St. Andrews, the mature "caddie" who accompanied him remarked, "Ye may be guid eneugh, Professor, at teaching laddies Greek; but gouf needs a heid." Professor Mosso is clearly of the "caddie's" opinion.

A frequent defect in modern gymnastic institutions—and not Italian only—is the *locale* in which the exercises take place. This, often confined and sparingly ventilated, more than neutralises whatever good may survive the frequent faultiness of the methods pursued. From this consideration Professor Mosso proceeds to that of the necessity of gymnastic as a means of combating the insanitary influences, always on the increase, of life in industrial and rapidly over-populated cities. Physical education, he concludes, to

Digitized by Google

be complete, must take in not only the muscular development, but that of other organs. True and healthful gymnastics must be diversified. He appeals to the municipalities of his country to aid in this salutary innovation by giving suitable *locales* for such exercises. But in order that physical education should start fair and advance beneficially, the Government should acquire a just notion of the physiological conditions of the youth frequenting school, so as to modify the hours of attendance, and appoint masters capable of teaching the true "recreative gymnastic," abandoning at once all traditional pedantries, fraught as these are neither with permanent robustness nor general vigour. "E un apostolato," says Signor Mancini, echoing Professor Mosso, "ed una missione degna di ogni uomo di cuore;" and we hope this "crusade," this "mission" of healthily rehabilitating the youth of Italy—aye, and of other countries—may soon find its proper instrument in an enlightened and practical system of "reform in athletics."

SOCIETY FOR THE STUDY OF INEBRIETY.

IN the large room of the Medical Society of London, on Tuesday last, this Society held its eighth annual meeting. The president, Dr. Norman Kerr, after a service of non-intoxicating refreshments, gave some particulars of an appeal he had made to the various temperance and allied societies on behalf of compulsory legislation for the habitual drunkard. Hitherto the temperance and general philanthropic bodies had opposed all such legislation, but the reception of this appeal revealed a marked change. Such great temperance bodies as the Church of England Temperance Society had thoroughly adopted the compulsory platform, recognising a large number of inebriates not as willing offenders but as impelled by a physically diseased condition. This influential Association had formally endorsed the platform of the Inebriety Society, and had taken active steps in agitating a change in the law. Other societies which did not make any official pronouncement on legislation had also approved the proposed actions. The secretary of the Band of Hope Union had said to him (Dr. Kerr) that the disease aspect of inebriety and compulsory legislation dealing with it were now fully accepted. The various female associations had been specially emphatic and unanimous in approval of the Society's legislature proposals. A number of large towns had also resolved to petition Parliament on the subject. Dr. Usher, F.R.G.S., of Melbourne, read a paper on "Some New Methods of Healing Alcoholism, with a theory based upon microscopical and other investigations as to the pathological conditions of the blood, and suggestions as to treatment."

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

On Diphtheria in St. George's, Hanover-square, by Mr. SWEETING.—The occurrence of diphtheria at Bourdon-buildings in the above-named parish was made the subject of inquiry by Mr. Sweeting on behalf of the Local Government Board. The buildings in question belong to a company, and they consist of twenty-four lettings. There was no special overcrowding, and, speaking generally, no particular sanitary defects were noticeable. But, commencing on Oct. 20th, diphtheria had prevailed there during the autumn months, and there had also been cases described under such terms as "tonsillitis." Indeed, out of twenty-three cases, eight were of such a character as to have remained unnotified. All the conditions under which diphtheria and allied sore-throat are known to prevail were investigated; but it was not easy to determine any particular cause as influencing the spread of the disease except school attendance; and it soon appeared that nearly the whole prevalence was related to attendance at one particular school. In the end Mr. Sweeting arrived at the conclusion that the recognised diphtheria had been preceded by occurrences of minor sore-throat ailment; that the disease had no relation to sanitary circumstances, to special milk services, or to disease in the lower animal; that there was a disproportionate incidence of the disease on school attendants, with an excessive incidence on attendants at one special school, and evidence as to the absence of children from this school from time to time owing to affections of the throat, together with proof of return to school in various stages of recovery. In this latter way personal infection through school attendance operated to maintain the prevalence. Precautions were taken to deal with the disease; but it is suggested that longer exclusions from school of affected persons might have helped to extinguish the disease at a much earlier date. Such exclusion, to be successful, must in every case be the result of action by the sanitary authority itself, and it is only likely to be efficient if it is based on the recommendation of the local health officer, who, in turn, must be kept apprised of every fresh occurrence of disease by means of immediate notification.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Ashton-in-Makerfield Urban District.—The death-rate for this district reached 22·7 per 1000 last year, and we can hardly regard the zymotic rate of 2·3 as a small one, especially when it is remembered that for so small a population it has averaged 2·8 during the previous ten years. The infantile death-rate is distinctly excessive, and it is unsatisfactory to read that nuisances which have been associated with enteric fever remain undealt with. The midden-privy system is badly managed and is a cause of nuisance; but at the same time Mr. Nathan Hannah says that good work is carried on, that the sewers have been carefully attended to, and that the hospital has been improved. What is evidently wanted is a detailed record of the sanitary circumstances of every house in the district, but the only thing the authority have done by way of setting a systematic inspection on foot has been to talk about it for "two or three years."

Poole Urban and Port Districts.—The zymotic rate for this district was low in 1891, and the general death-rate was 14·2 per 1000. After discussing certain occurrences of disease, Dr. Lawton speaks of the scavenging and flushing as being well carried out, of a good water-service, of regular inspection of the district, and of prospective improvements as to sewerage. The number of infectious cases coming under notice is not given, but the infectious hospital was not used. In the port 145 inspections of vessels were made, Dr. Lawton undertaking those in which medical points seemed to arise, and as the result improvements in shipping were ordered and effected.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6131 births and 4346 deaths were registered during the week ending April 2nd. The annual rate of mortality in these towns, which had been 24·8 and 22·3 per 1000 in the preceding two weeks, further declined to 22·2 last week. In London the rate was 21·4 per 1000, while it averaged 22·8 in the thirty-two provincial towns. The lowest rates in these towns were 14·7 in Croydon, 16·1 in West Ham, 17·1 in Gateshead, and 18·3 in Bradford; the highest rates were 26·5 in Swansea and in Burnley, 26·7 in Halifax, 26·8 in Preston, and 28·1 in Manchester. The 4346 deaths included 427 which were referred to the principal zymotic diseases, against 477 and 435 in the preceding two weeks; of these, 170 resulted from whooping-cough, 134 from measles, 42 from diarrhœa, 33 from scarlet fever, 30 from diphtheria, 16 from "fever" (principally enteric), and 2 from small-pox. No fatal case of any of these diseases was registered in Norwich; in the other towns they caused the lowest rates in Bolton, Gateshead, and Halifax, and the highest in Salford, Liverpool, Sheffield, and Wolverhampton. The greatest mortality from measles occurred in Birkenhead, Birmingham, Sheffield, Liverpool, and Wolverhampton; from scarlet fever in Birkenhead and Cardiff; from whooping-cough in Brighton, Bristol, Salford, Huddersfield, Sheffield, Swansea, and Wolverhampton; and from diarrhœa in Preston and Blackburn. The mortality from "fever"

showed no marked excess in any of the thirty-three large towns. The 30 deaths from diphtheria included 15 in London, 3 in Manchester, 2 in Birmingham, 2 in Bradford, and 2 in Newcastle-upon-Tyne. Two deaths from small-pox were registered in London, but not one in any of the thirty-two provincial towns; 43 cases of this disease were under treatment in the Metropolitan Asylum Hospitals on Saturday last (of which 11 were admitted during the week), and 7 in the Highgate Small-pox Hospital. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 1227, against 1230 and 1226 on the preceding two Saturdays; 139 new cases were admitted during the week, against 146 and 126 in the previous two weeks. The deaths referred to diseases of the respiratory organs in London, which had been 523 and 466 in the preceding two weeks, further declined last week to 430, and were 44 below the corrected average. The causes of 78, or 1·8 per cent., of the deaths in the thirty-three towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Cardiff, Croydon, Leicester, Leeds, and in six other smaller towns; the largest proportions of uncertified deaths were registered in West Ham, Preston, Huddersfield, Bradford, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 24·2 and 23·4 per 1000 in the preceding two weeks, further declined to 21·2 during the week ending April 2nd, and was 1·0 per 1000 below the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 15·6 in Leith and 17·1 in Aberdeen to 23·5 in Glasgow and 27·5 in Perth. The 589 deaths in these towns included 24 which were referred to whooping-cough, 15 to measles, 8 to "fever," 7 to diphtheria, 6 to scarlet fever, 5 to diarrhœa, and not one to small-pox. In all, 65 deaths resulted from these principal zymotic diseases, against 71 and 69 in the preceding two weeks. These 65 deaths were equal to an annual rate of 2·3 per 1000, which slightly exceeded the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of whooping-cough, which had been 28 and 34 in the preceding two weeks, declined again last week to 24, of which 11 occurred in Glasgow, 3 in Edinburgh, and 3 in Dundee. The deaths referred to measles, which had declined in the previous three weeks from 16 to 12, rose again to 15 last week, and included 13 in Glasgow. The 8 fatal cases of "fever" showed a further increase upon recent weekly numbers; 3 occurred in Glasgow, 2 in Edinburgh, and 2 in Dundee. The deaths from diphtheria, which had been 5 and 8 in the preceding two weeks, were 7 last week, and included 3 in Glasgow and 2 in Edinburgh. Of the 6 fatal cases of scarlet fever, 5 were recorded in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 183 and 181 in the preceding two weeks, further declined last week to 158, and were 8 below the number in the corresponding week of last year. The causes of 74, or nearly 13 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had increased in the preceding four weeks from 32·7 to 40·1 per 1000, declined again to 37·3 during the week ending April 2nd. During the thirteen weeks of the quarter ending on Saturday last the death-rate in the city averaged 38·4 per 1000, the rate for the same period being 28·2 in London and 19·8 in Edinburgh. The 250 deaths in Dublin during the week under notice showed a decline of 19 from the high number in the preceding week, and included 24 which were referred to measles, 3 to whooping-cough, 2 to diarrhœa, 1 to "fever," and not one either to small-pox, scarlet fever, or diphtheria. In all, 30 deaths resulted from these principal zymotic diseases, equal to an annual rate of 4·5 per 1000, the zymotic death-rate during the same period being 2·6 in London and 1·8 in Edinburgh. The fatal cases of measles, which had been 12 and 22 in the preceding two weeks, further rose to 24 last week, and exceeded the number recorded in any week since August, 1887. The deaths referred to whooping-cough, which had been 5 in each of the previous two weeks, declined to 3 last week. The 2 fatal cases of diarrhœa were within one of the number returned in the preceding week, and the death referred to "fever" corresponded with the number in the previous week. The 250 deaths in Dublin last week included 43 of infants under one year of age, and 56 of persons aged upwards of sixty years; the deaths of infants exceeded the number in any recent week, while those of elderly persons showed a marked decline. Three inquest cases and 5 deaths from violence were registered; and 91, or more than a third, of the deaths occurred in public institutions. The causes of 25, or 10 per cent., of the deaths in the city last week were not certified.

VITAL STATISTICS OF CALCUTTA AND ITS SUBURBS.

Dr. W. J. Simpson, the Health Officer for Calcutta, in his official memorandum for December last, reports that the total number of births registered during the month was 894, against 783 in the preceding month, giving an annual ratio of 22·9, against 20·1 per 1000 of the population. Of the 894 births, 449 were males and 445 females. The total number of deaths (exclusive of still births) registered in December was 1380 against 1282 in the preceding month, showing an annual ratio of 35·5 per 1000. The proportion of male to female deaths was as 136 to 100. The monthly total exceeds all the corresponding figures of the past decade, excepting 1881 and 1882, and also exceeds the decennial mean by 93. There were 98 deaths from cholera, against 152 in the preceding month, less than the average of the past decade by 80. No deaths from small-pox, but those from fever amounted to 536, against 513 in the preceding month, and in excess of the corresponding figures for the past ten years. There were 47 deaths from tetanus during the month, 41 of which were in infants under one year of age. In the amalgamated area of suburbs there were 486 births registered in December, giving an annual ratio of 27·1 per 1000 of population. The total number of deaths registered was 879, giving an annual ratio of 49·0 per 1000. Of these deaths, 49 were from cholera, 388 from fevers, 154 from bowel complaints, 52 from tetanus, 7 from injuries, and 229 from other causes. There were no deaths from small-pox in the suburbs during the month. According to the weekly return of deaths for the week ending Jan. 23rd, 1892, the latest return received by us, the total number of deaths for the town of Calcutta registered during the week was 309. The general death-rate of the week was 34·5 per 1000 per annum, against 28·2, the mean of the last five years. The general death-rate of the week for the amalgamated area was at the rate of 46·3 per 1000 per annum, against 37·8, the mean of the last five years. The general death-rate of the combined area is equal to 38·2. The prominent and recurring features in these returns from Calcutta and its suburbs are the prevalence of fevers (presumably malarial in their nature), bowel complaints, and tetanus, especially among the infant population.

THE SERVICES.

WE regret to announce the death of Deputy-Surgeon-General Dr. Thomas Fraser from pneumonia, on the 3rd inst., at Exeter. The deceased officer had long retired from the Service. He was for a long time the surgeon of the 10th Hussars, and subsequently was in medical charge of the Royal Military College at Sandhurst. Deputy-Surgeon-General Fraser was very popular and much esteemed whilst in the Medical Service, and the news of his death will be received with much regret by those to whom he was known.

Brigade-Surgeon-Lieutenant-Colonel T. Maunsell, in charge of the 2nd Station Hospital at Aldershot, in anticipation of promotion to Surgeon-Colonel, succeeds Surgeon-Major-General G. L. Hinde, Principal Medical Officer, South-Eastern District, who shortly retires.

ARMY MEDICAL STAFF.—We understand that in future every candidate for a commission in the Army Medical Staff will be required to possess, in addition to the qualifications previously laid down, a certificate of having acted as medical clinical clerk for six months and as surgical dresser for another six months, not less than three months of each period being spent in hospital wards; also a certificate of having attended not less than three months' instruction at an ophthalmic hospital, whose course shall include instruction in the errors of refraction.

Digitized by Google

Surgeon-Major W. T. Johnston, doing duty in the Belgaum and Bangalore Districts, Madras command, has been appointed to the charge of the Station Hospital, Rangoon; Surgeon-Major A. W. Carleton has been transferred from the Station Hospital, Rangoon, on appointment to the charge of the North Station Hospital at Secunderabad, Madras command; Surgeon-Captain F. T. Skerrett has been transferred for duty in the Madras District from the Station Hospital at Wellington; Surgeon-Lieutenant-Colonel H. W. A. Mackinnon, D.S.O., will, on transfer from Canterbury to Aldershot for duty, be appointed to the charge of the North Camp Hospital, vice Brigade-Surgeon-Lieutenant-Colonel F. Howard; Brigade-Surgeon-Lieutenant-Colonel F. B. Scott, C.M.G., takes charge of the 2nd Station Hospital, vice Brigade-Surgeon-Lieutenant-Colonel T. Maunsell; Surgeon-Captain C. W. Thiele, stationed at the 3rd Station Hospital, Aldershot, has been placed under orders for embarkation for the West Coast of Africa; Surgeon-Captain J. W. Jennings has proceeded from Worcester to Carnarvon to assume medical charge of the 4th Battalion Royal Welsh Fusiliers, and Surgeon-Captain R. J. Windle, from Chester to Beaumaris, in medical charge of the Royal Anglesea Engineering Militia; Surgeon-Captain T. Archer has been struck off the strength of the S.E. District, on proceeding to Bermuda; Surgeon-Captain H A. de Lom has been posted to the Station Hospital, Western Heights, Dover; Surgeon-Captain R. Kirkpatrick has joined at Easter-road Barracks for duty from Edinburgh Castle, and Surgeon-Captain G. Wilson has joined in his place from Piershill; Surgeon-Captain G. E. Moffett has been transferred from Perth to Fort George, and Surgeon-Captain W. G. Birrell from Fort George to Easter-road Barracks; Surgeon-Captain L. Nash proceeded on the 25th ult. to Hebburn, in medical charge of troops, and Surgeon-Captain S. R. Wills has been posted to Newcastle-on-Tyne; Surgeon-Major J. E. Nicholson has joined the Citadel, Plymouth, for duty; Surgeon-Captain J. H. Brannigan has arrived at Devonport for duty; Surgeon-Captain G. G. Adams has been transferred to Horfield from Cardiff; Surgeon-Captain T. W. Gibbard has joined at Winchester, from Portsmouth; Surgeon-Captains R. C. Johnston and R. G. Thompson have joined the Thames District for duty.—Surgeon-Major-General A. M. Tippetts, having attained the age of sixty, has been placed on retired pay.—Surgeon-Major T. J. Gallwey, M.D, Medical Staff, having left for Cairo to take up his appointment in the Egyptian Army, will now be seconded.

ARMY MEDICAL RESERVE OF OFFICERS. — Surgeon-Captain Alfred Herbert Marsh, 3rd Volunteer Battalion, the Cheshire Regiment, to be Surgeon-Lieutenant (dated April 6th, 1892).

NAVAL MEDICAL SERVICE.—The undermentioned Surgeons have been promoted to the rank of Staff Surgeon in Her Majesty's Fleet:—William Manley Lory and William Spencer Lightfoot.—The following appointments have been made at the Admiralty:—Staff-Surgeon Wm. S. Lightfoot to the *Philomel* (dated March 31st, 1892); Surgeons: Edwd. Cooper to the *Victory* (dated April 4th, 1892); Joseph C. Wood to the *Assaye* (dated April 5th, 1892); Richard F. Bate to the *Champion* (undated).

VOLUNTEER CORPS.—*Royal Engineers* (Fortress and Railway Forces): 1st Aberdeenshire: William Sinclair, M.B., to be Surgeon-Lieutenant (dated April 2nd, 1892).—*Rifle:* 1st Surrey (South London): Surgeon-Lieutenant C. S. Smith to be Surgeon-Captain (dated April 2nd, 1892).—1st Volunteer Battalion the Royal Sussex Regiment: Charles William James Chepmell, M.D., to be Surgeon-Lieutenant (dated April 2nd, 1892).—20th Middlesex (Artists'): Surgeon-Captain A. R. F. Evershed resigns his commission (dated April 2nd, 1892).

VOLUNTEER MEDICAL STAFF CORPS.—The Manchester Division: Geo. Clements Richardson, Gent., to be Surgeon-Lieutenant (dated April 2nd, 1892).

ESSEX AND HERTS BENEVOLENT MEDICAL SOCIETY.—The annual report for 1891 of this Society, for the relief of the widows and orphans of medical men in the counties of Essex and Hertford, shows that the total grants for the year amounted to £375. The capital stock, invested in Consols, was £10,053.

THE OPIUM QUESTION.

To the Editors of THE LANCET.

SIRS,—The "opium controversy" has of late attracted considerable attention. It was the subject of an article that appeared in THE LANCET a few weeks ago, and also of a long discussion in the Indian Section of the Society of Arts. A circular has also been widely distributed amongst members of the medical profession, of which I have received a copy, asking us to subscribe to certain propositions regarding the effects of the consumption of opium upon the people of India, and to sign a memorial recommending to the Government of India that the growth and sale of opium in India should be prohibited by law. This document I have not felt myself able to sign, as I am convinced that many of the statements in the memorial and in the covering letter are erroneous, and founded upon imperfect knowledge. Probably a large proportion of the 5000 members of the medical profession whom you state to have signed the memorial have done so on hypothetical grounds, and without any direct or personal knowledge of its merits. I have had rather a long experience of medical practice in India, having had charge of native hospitals, dispensaries, and gaols in nearly all parts of the Bengal Presidency, in the hills, in the Punjab, the North-West Provinces, Lower Bengal, and Orissa, and I have always mingled freely with natives of all classes; so that I have had pretty full opportunity of judging of the effects of the use of opium on the health and well-being of the people generally, and, as the subject is of the greatest medical interest, I venture to ask you to accord me a small space in your influential journal for this letter. I do not propose to enter into the political and financial side of the question. That I would leave to others who have more special knowledge on such matters, and are more capable of forming a correct judgment. Unless, however, it can be clearly established—and this is a medical question—that the use of opium, as we find it in India, leads to anything like common or widespread injury to either the moral or physical well-being of the people, we should, indeed, hesitate before we advocate the giving up a large source of revenue which presses upon no one, and in its place lay additional taxation on, perhaps, the poorest, but at the same time the most patient, thrifty, and industrious, peasantry in the world. It would indeed be a most cruel and tyrannical exercise of England's almost unlimited power in India, perhaps only to remove a sentimental wrong.

In bringing to notice some of the medical and sanitary aspects of the question, I will confine myself chiefly to matters that have come under my personal knowledge and observation. It is well known that the use of opium by the people of India is far from being general or universal. It is very much restricted to certain classes and to certain localities; of those who use opium, some smoke and some eat the drug. As a rule, when the people are in the habit of taking opium they do so in great moderation; there is no general tendency to exceed, any more than with the majority of people at home who take their daily glass or two of wine or beer there is a tendency to drink in excess. In the same way it is, I am convinced, an erroneous notion to suppose that in the moderate quantity in which it is usually taken opium has a deleterious effect upon the health or physique of the people. The Sikhs in the Punjab, perhaps the most hardy, vigorous, and warlike race in India, commonly take opium, and they certainly show no signs of deterioration. Again, the palki-bearers of Behar and Goruckpore, men of small stature and slight build, are perhaps capable of as great or greater physical exertion as any class of men in the world, and that on an amount of nourishment that in this country would hardly satisfy a child. They nearly all smoke opium. I have known a set of twelve men—and eight men will do equally well—carry me in a palanquin a distance of forty miles in a little over ten hours. Of course they take turns to carry, four and four about, but all the men run

THE OPIUM QUESTION

To the Editors of THE LANCET.

SIRS,—The "opium controversy" has of late attracted considerable attention. It was the subject of an article which appeared in THE LANCET a few weeks ago, and has also been the discussion in the Indian Section of the Society of Arts. A circular has also been widely distributed amongst members of the medical profession, of which I have received a copy, asking us to subscribe to certain propositions regarding the effects of the consumption of opium upon the people of India, and to sign a memorial recommending to the Government of India that the growth and sale of opium in India should be prohibited by law. This document I have not felt able to sign, as I am convinced that many of the statements in the memorial and in the covering letter are misleading and founded upon imperfect knowledge. From the large proportion of the 5000 members of the medical profession whom you state to have signed the memorial, I have done so on hypothetical grounds, and not from any direct or personal knowledge of its merits. I had rather a long experience of medical practice in India, having had charge of native hospitals, dispensaries and gaols in nearly all parts of the Bengal Presidency, the hills, in the Punjab, the North-West Provinces, Lower Bengal, and Orissa, and I have always mingled freely with natives of all classes; so that I have had pretty full opportunity of judging of the effects of the use of opium on the health and well-being of the people generally, and, as the subject is of the greatest medical interest, I venture to ask you to accord me a small space in your influential journal for this letter. I do not propose to enter into the political and financial side of the question. That I would leave to others who have more special knowledge on such matters and are more capable of forming a correct opinion. Unless, however, it can be clearly established—and it is a medical question—that the use of opium is found it in India, leads to anything like comparable widespread injury to either the moral or physical health of the people, we should, indeed, hesitate before advocate the giving up a large source of revenue which presses upon no one, and in its place lay additional burdens on, perhaps, the poorest, but at the same time most patient, thrifty, and industrious, peasantry in the world. It would indeed be a most cruel and tyrannical measure remove a sentimental wrong.

In bringing to notice some of the medical and social aspects of the question, I will confine myself to matters that have come under my personal knowledge and observation. It is well known that the use of opium by people of India is far from being general or universal; very much restricted to certain classes and in localities: of those who use opium, some smoke and eat the drug. As a rule, when the people are in the taking opium they do so in great moderation; there general tendency to exceed, any more than with the of people at home who take their daily glass or two of beer there is a tendency to drink in excess. In this way it is, I am convinced, an erroneous notion to that in the moderate quantity in which it is usually opium has a deleterious effect upon the health of the people. The Sikhs in the Punjab, perhaps the hardy, vigorous, and warlike race in India, consume opium, and they certainly show no signs of degeneration. Again, the palki-bearers of Behar and Gorakpore are small stature and slight build, are perhaps capable greater physical exertion as any class of men in the world, and that on an amount of nourishment that country would hardly satisfy a child. They usually have known a set of twelve men—and eight will do equally well—carry me in a palanquin a little over ten hours. Of course they miles in four and four about, but all the

through the whole distance. They always halt two or three times during the journey and pass round the opium pipe, and each man takes a few whiffs, and then on again as fresh as if they were just starting. No one can say the opium injures their health or stamina. It is, however, especially in very malarious and feverish localities that opium is most generally used, and it seems then to be almost a necessity. In Assam and Eastern Bengal its use is almost universal, and in Orissa—along the swampy, feverish coast, teeming, one may say, with malaria—nearly all take opium. "It keeps us alive," they say, and, from what I saw of the people and the prevalence of fever amongst them, I believe that it did so. I cannot say that a dose of opium will either prevent or cure a paroxysm of malarious fever as quinine will; but the opium seemed to enable a man to resist the fever and to get through his day's work in spite of it. It may be true that quinine and other drugs would answer better as anti-periodics, but how could these poor peasants ever get enough of such expensive drugs. They can get for a few annas—say, for sixpence, the price of two or three febrifuge doses of quinine—one *tola*, or 180 grains, of opium, enough to last a man for months. It may, I think, be almost accepted as a proof of the benefit of opium in counteracting the bad effects of malaria that we so generally find that in malarious regions the people take opium. I remember the time when its use was very general in the fens of Lincolnshire and Huntingdon, where on market days one would see the country people going in numbers to the chemist's shop, place their penny on the counter, and take up a small packet which contained the week's supply of opium. Whether there is anything of the kind now I do not know. The fens have been drained since then, and perhaps ague and opium-eating are both things of the past.

There is another point in connexion with the use of opium in India which has not, I think, been fairly considered by those who would prohibit it. The peasants of India generally are very poor. They live and toil (and for them there are no restrictions to eight hours' work a day, and no Sunday or weekly holidays) on an almost incredibly small amount of nourishment, according to our English ideas. A daily allowance of 1½ lb. of rice or flour, a little vegetable and butter, and a pinch of salt and spices, is pretty well the whole food of a working man, and there seems to be no doubt that where food is scanty a small quantity of opium tends to prevent rapid waste of tissue, and enables a man to sustain life and vigour on such small allowance of food. I cannot help believing that if the use of opium in India were prohibited, it would inflict an incalculable amount of suffering and injury upon vast numbers of our Indian fellow subjects. Of course, as with everything else, the use of opium may be abused, and no doubt a certain proportion of the opium consumers take it in excess and ruin their minds and bodies. The opium dens and hells in our large towns in India, as in London, show this. Even then the effects of opium are not nearly so bad as those of alcohol. The opium debauchee at least injures himself only, or perhaps those depending upon him. The drunkard not only ruins his own life, but is a danger to his neighbours as well, and drink is the cause of most of the crime in this country. Opium practically leads to no crime, and there is little doubt that if the use of opium could be prevented in India, some other and probably far more deleterious nerve stimulant or sedative, as alcohol or *bhang* (Indian hemp), would take its place. I think that few even of the most sincere supporters of temperance, amongst whom I humbly hope I may include myself, would advocate the passing of a law in England forbidding the sale or consumption of alcoholic drinks, even if such a course were possible. To carry out such a law in India in respect to opium would be equally impossible; I doubt if even our all-powerful Government could do so. Every man in India who wished for it would cultivate his own little patch of poppy, and it would be difficult even for the most autocratic Government to keep watch over and punish millions of people for doing what they thought right; but could such a law be enforced I am strongly of opinion that we should not, in the language of the memorial above noticed, be "seeking the welfare of the people of India."

I am, Sirs, yours faithfully,

HENRY CAYLEY, F.R.C.S.,
Indian Medical Service (retired).

Netley, March 26th, 1892.

DENHOLM *v.* TAIT.

To the Editors of THE LANCET.

SIRS,—I think you will admit, after reading my letter, that I am entitled to make a few comments in your columns upon the above case, especially since Mr. Lawson Tait has thought proper to address a letter to *The Times* on the subject. The action for libel I felt compelled to bring against Mr. Tait originated in a letter he addressed to the husband of a lady who had died forty-four hours after being operated upon by him for uterine myoma. In this letter the following passage appeared: "The immediate cause of the unfortunate result is the rupture of a bloodvessel at or near the spot where the electrical needles caused so much damaging inflammation and sloughing. Had she never been submitted to that treatment the case would have been a straightforward one, and her recovery almost certain." As I had been solely responsible for the application of this electrical treatment, the husband brought the letter to me with a natural desire to be satisfied how far the accusation was correct.

For the purpose of vindicating my professional reputation, I requested and obtained permission for a post-mortem examination. This examination was conducted by three experienced pathologists totally unknown to me, and the result was to the effect that the patient had died not from hæmorrhage, but from septic peritonitis. I immediately wrote to Mr. Tait to ask him whether he still persisted in his opinion, and he replied not only that he did, but that he was prepared to substantiate it. I was then advised that my only course was to institute an action for libel. The trial lasted three days, and the evidence completely and satisfactorily proved that no electrical needles had ever been used, that the electrical treatment had nothing whatever to do with the cause of death, and that the patient had lost her life from septic peritonitis, entirely due to the operation performed by Mr. Tait. At the conclusion of Mr. Tait's evidence my counsel suggested to me that as Mr. Tait had declared that the letter he sent was not the one he intended, that as I had been fully exonerated by Mr. Tait from all blame, and that as the jury would have to find Mr. Tait guilty of stating that which he knew to be untrue before they could award me a verdict, I might consent to the withdrawal of a juror, with a full and complete understanding that all imputations were withdrawn on both sides. To this I assented, considering, as I still consider, that I was making a generous concession. Mr. Tait's counsel expressed himself as highly satisfied with the withdrawal of the action, and the judge concurred in the prudence of the course I had taken. I also felt satisfied that the dispute had been settled in a manner mutually satisfactory and honourable. Three days later, however, Mr. Tait addressed a letter which appeared in *The Times* of March 29th, in which he stated that he regarded the result of the trial as a "victory!' and reiterated his attack upon me by saying that he reasserted everything he had asserted before, and that he had withdrawn nothing; that is to say, that he still believed that "the immediate cause of death was hæmorrhage due to the use of electric needles." After the appearance of this letter the judge who had tried the action was appealed to in court by my counsel, and requested to state what his impression was of the terms of settlement. His lordship replied that he understood Mr. Tait to withdraw all imputations, and to say that he entirely exonerated me from any negligence or any want of skill in my application of the electric treatment. I am quite willing to leave the issue for your readers to decide whether or not Mr. Tait was justified when he stated in *The Times* that "so far as I am concerned, and by my counsel, I withdraw nothing."

I am, Sirs, yours faithfully,

Manchester, April 6th, 1892. ANDREW DENHOLM, M.D.

To the Editors of THE LANCET.

SIRS,—In your article on this subject you inadvertently do me an injustice which I am sure you will permit me to correct. You say that "Mr. Tait at the trial still spoke as if he believed that a hæmatocele existed, and might have been found if looked for." There were four witnesses besides myself waiting to prove that they saw the hæmatocele—viz., Mr. Christopher Martin, Mr. Charles Martin, Nurse Trease (three

Digitized by Google

members of my staff), and Mr. Alfred Freer, surgeon, of Stourbridge — an altogether independent witness who happened to be present at the operation. With the details of this particular hæmatocele and how it killed this patient I shall not trouble you now, for a complete story of this remarkable case will be laid before the profession at as early a date as possible, as an illustration of how important these accidents are and how strangely they have been overlooked. In passing I may say that this is the only instance in which I have known a hæmatocele to prove fatal; but that it did so will elsewhere and in due course be shown by Mr. Christopher Martin, who hardly left the patient from the time of the operation till her death. The case in this as well as in certain other respects is unique.

That the course adopted of consenting to withdraw a juror was a mistake you may well believe, and at first I was very much averse to it, as I wanted the whole thing thrashed out and a verdict of the jury taken; but very many reasons in favour of it can be given, which, however, do not concern the issue raised by your article or require discussion in a medical journal. The reason which chiefly influenced me was that the case had been hurried on to trial with a precipitance enormously to my disadvantage; so that the plaintiff's answers to interrogatories administered on my behalf did not reach us until the case was on the eve of going into court. Not till then did it dawn upon me or upon my advisers that I was practically being put in the dock on two criminal charges, that I had wilfully and maliciously misstated the cause of the patient's death, and that I had recklessly and improperly operated on her. I feel almost certain that most of the plaintiff's witnesses did not realise the full effect of the course they had thought fit to take until they heard my counsel's opening speech, or I am sure they would never have given such evidence as they did, particularly the three young gentlemen who spoke so smilingly of the so-called post-mortem examination, to which, as you emphatically point out, I was not invited.

Further, another action was pending, Tait *v.* Payne. The husband of the patient, also acting on the lines above indicated, stopped the cheque which he had given me after the operation. I entered an action for the recovery of the fee, on the trial of which you will see that I would have had a far better chance of fighting out the whole question, especially as that trial would have taken place in London. The end came, however, with great speed and perfect certainty. No sooner was Denholm *v.* Tait settled than the solicitors for the defendant in Tait *v.* Payne came and made proposals for a settlement. This I refused absolutely, save on the payment of the full fee with costs of the action, and these terms were promptly conceded.

I am, Sirs, yours faithfully,

Birmingham, April 5th, 1892. LAWSON TAIT.

*** We insert the above letters, but it must be clearly understood that we cannot publish any more correspondence on the subject.—ED. L.

"PYRAMIDAL CATARACT."

To the Editors of THE LANCET.

SIRS,—In your last issue you published a letter from Mr. P. H. Mules commenting on a paper of mine which I read before the Ophthalmological Society on the minute anatomy of pyramidal cataract. It is a great pity Mr. Mules was unable to be present at the meeting to hear my paper in full and to see my specimens. Had he been, he would have seen that I did not "divide my cases arbitrarily into groups," but took them according to the time that had elapsed between the formation of the cataract and the excision of the eye—that is, in the order of the age of the opacities. If Mr. Mules had not mislaid his copy of Dr. Samelson's paper, he would have found on referring to it that Professor Schweigger concluded his account of the microscopical examination of the specimen as follows:—"To the question, then, which here chiefly concerns us, whether the cone was interior or exterior to the capsule, we do not obtain a satisfactory answer." This was a point upon which my specimens supplied very definite evidence. The statement "that in the majority of cases pyramidal cataract is found associated with a perfectly transparent cornea" has been made by others besides Mr. Mules, and I presumed that in his article it was a quotation, for it was placed between inverted commas. What I said was quite logical: that before this statement can be accepted as proved it would be necessary to examine pathologically a large number of eyes with opaque corneæ so ascertain the condition of the lenses in them. In the six cases I brought before the Society the cornea was the seat of old or commencing opacity. If these eyes had only been examined clinically the fact that they contained pyramidal cataracts would not have been known.

Mr. Mules finally refers to two cases he has recently operated on in which the pyramid lay outside the capsule. He does not say that he arrived at this conclusion from a microscopical examination of it. Granting, however, that in each case it was outside the capsule, they cannot then be spoken of as opacities of the lens, and were not therefore cataracts. One of the objects I had in view in reading my paper was to confirm definitely that there are opacities at the anterior pole of the lens situated within the capsule, and to which the term "anterior polar cataract" or "pyramidal cataract" can be truly applied. Von Ammon long ago pointed out that portions of the anterior fibro-vascular sheath of the lens may persist. Doubtless sometimes these persistent membranes may closely simulate a true pyramidal cataract. Our object should be to differentiate these two classes of cases and to call the former what they really are—persistent pupillary membranes, not cataracts.

I am, Sirs, yours truly,

E. TREACHER COLLINS.

Devonshire-street, W., April 4th, 1892.

CYSTIC GOITRE.

To the Editors of THE LANCET.

SIRS,—I have read with much interest Mr. O'Reilly's successful case of a large goitre treated by injections and subsequent operation; the more so, perhaps, as I have been using injections in a similar manner, and with a similar double syringe, for some thirty years. I began the use of this method in rather recent cases, withdrawing a small quantity of the liquid and replacing it with an equal amount of alcohol. The idea was to alter the specific gravity of the fluid in the cyst with a view of promoting its absorption, and in moderately recent cases success was obtained. But in more advanced cases not much effect followed. Iodine was tried with a somewhat similar result. Prior to this I had employed this method in pleuritic effusion; but the introduction of the aspirator showed that these may be dealt with much more vigorously. In large cystic goitres the small hypodermic syringe is hardly powerful enough, and in all cases the fine needle is apt to become blocked on account of the flocculent nature of the fluid to be withdrawn. The aspirator needle can be fitted up for the purpose, or, better still, a shorter one of ample bore. Some of the visitors and pupils at the Throat Hospital during the many years I acted as physician to that institution must have seen me employing this method, and the instruments may probably still be at that hospital.

I am, Sirs, yours faithfully,

Deanery-street, Park-lane, April 4th, 1892. PROSSER JAMES.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

South-West Lancashire Spring Assizes.

LORD CHIEF JUSTICE COLERIDGE is presiding at the present spring assizes, and it is hoped in legal circles that his lordship's visit, which is an unusual event on this circuit, will lead to a reform in our present assize arrangements. The grievances of barristers and jurors are more in evidence than the grievances of witnesses, especially medical witnesses. The local authorities have been ordered to provide better accommodation at the courts for the prisoners waiting their trial, but apparently no notice has been taken of the entire want of any provision at all for medical and other witnesses waiting their appearance before the grand jury. It has been repeatedly stated in previous letters that the medical and other witnesses are all waiting at the top of a flight of stairs, which, with the landing and an adjacent lobby, are the only accommodation for them. One learned judge (Mr. Justice Wills) himself made a point of inspecting personally the places in which prisoners were lodged before entering the dock. Is it too much to hope that

the same learned or some other judge will do the same kind office for witnesses. An inspection of the witnesses' room near the Crown Court and of the outside of the grand jury room at the opening of the assizes, would probably effect in a few minutes that which years of patient reiteration may never accomplish.

More Frequent Assizes required.

The population of Lancashire is rapidly approaching that of London, and yet we have only four assizes in Liverpool and Manchester, while in London there are monthly sittings at the Central Criminal Court. The inconvenience of the present system is keenly felt by medical witnesses residing at a distance, who have to leave their practices and attend day after day for a remuneration which must leave them considerably out of pocket. The holding of an assize every two months would reduce this to a minimum, and would be only in accordance with modern progress.

A Heavy Calendar.

So heavy was the business at Manchester that the assizes in Liverpool had to be postponed for nearly a week, to the great inconvenience of many persons. The number of prisoners and that of civil causes to be tried here is unusually heavy, and both judges will have to sit early and late in order to finish before Easter.

Prevention of Cruelty to Children.

A public meeting was held in the Town Hall, Birkenhead, on the 2nd inst., under the presidency of the Mayor (Alderman Wilmer), for the purpose of forming a branch of the Liverpool Society for the Prevention of Cruelty to Children. The meeting was called in pursuance of an influentially signed requisition, and resolutions in favour of forming the proposed branch and of appointing an influential committee were carried unanimously. The Liverpool Society has done an excellent work in preventing one phase of cruelty—i.e., children of tender age trading in the streets in order to maintain drunken, idle, and cruel parents; and it is hoped that the Birkenhead branch will be equally successful.

Liverpool, April 5th.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

Newcastle Clinical Society.

THE last meeting of this Society for the session was held on Thursday last. Dr. James Aitchison showed three patients upon whom various joint excisions had been performed two years previously—viz.: (1) Excision of the knee—a female about twenty; (2) excision of wrist, also a female about the same age; (3) excision of ankle—a lad about fifteen, who was now able to take his part at football; amputation had been previously advised and declined in this case. Mr. Morrison showed for Dr. Drummond a case of muscular atrophy following influenza. Dr. H. S. Baumgartner brought forward a case of elephantiasis. Dr. George Murray showed for Dr. Beatley a specimen of pericarditis. Dr. J. A. Jackson read a paper on scarlet fever. The second of the course of sanitary lectures and demonstrations promoted by the Sanitary Institute and the Corporation of Newcastle was delivered last Saturday night at the Guildhall by Mr. A. Wynter Blyth, medical officer of health for St. Marylebone, his subject being House Drainage and Sanitary Appliances. A number of models and appliances were exhibited, and there was a large attendance.

"Milk and Water."

Dr. Armstrong, our medical officer of health for this city, says that the milk trade in Newcastle alone represents a sale of probably not less than 1,500,000 gallons per annum, costing the consumers about £100,000. At the same rate of calculation the amount sold yearly in the United Kingdom is about 250,000,000 gallons, representing a cost of £17,000,000. In 1889, 21 per cent. of the analysed samples of milk in London were adulterated to an estimated aggregate loss to the consumers of £50,000 per annum on an outlay of £2,000,000 sterling. If, as he says, even one-hundredth part of the so-called "milk" be in the form of water, the adulteration means an annual robbery of the Newcastle consumers to the tune of about £1000 and the British public of £170,000.

Middlesbrough and District.

Dr. Malcomson, the medical officer for the Rural Sanitary Authority, reports that during the whole year the health of the district had been very satisfactory, the death-rate only reaching 14·15 per 1000 per annum.—The Saltburn Convalescent Home is announced to be reopened on May 5th and 6th next. "The master masseur" (so says the local paper) has been holding forth to crowded audiences at West Hartlepool.—"The master" does not pretend that the system will completely cure a chronic complaint on being first applied (modest man!), but he maintains if the system is fully carried out it will restore the patient to a healthy condition. Cases of neuralgia and of deafness of fifteen years' standing are nothing in his way. The "master masseur" does not weary his audience by mere talking. A "really first-class concert" forms part of the evening's programme. "The master" himself also, it is said, contributes to the entertainment, showing no mean skill as a singer or reciter. "The master masseur" extracts teeth free of charge, whether he pulls one or a dozen from the same individual, while the banjo performers "soothe away all pain."—Dr. Townsend of Normanby, near Middlesbrough, was the recipient last week, on his return from his honeymoon, of an illuminated address and handsome presents for himself and Mrs. Townsend, subscribed for by over 400 miners of the district. Dr. R. W. Smeddle has also received a presentation in recognition of his services as a lecturer to the North-Eastern Railway Ambulance Class at New Shildon, near Darlington. At Monkwearmouth, Dr. H. Davis has also received a presentation as a token of appreciation of his services to the ambulance class.

The late Mr. John Bowes, Surgeon, of Richmond.

The remains of the late Mr. John Bowes of Richmond were interred in the family vault in that town on last Friday, amid every manifestation of respect. Mr. Bowes did not long survive his brother, who died last Christmas, at an advanced age. Mr. John Bowes died in the South of France, where he had been sojourning for his health for some time. He was thus the last of the well-known medical family, the Bowes of Richmond.

Mr. F. H. Homfray of Gainford, near Darlington, has again been awarded the Government grant for successful vaccination in the Teesdale district.

Newcastle-on-Tyne, April 6th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Extension of the Edinburgh Royal Infirmary.

A MEETING of the contributors to the Royal Infirmary was held last week to consider the proposed extension of the hospital, at which a report by a committee of contributors was submitted. The report dealt with the first plans submitted by the infirmary managers, which were not approved, and also with negotiations with the directors of the Sick Children's Hospital and with the governors of George Watson's Trust, the result of which was that both these bodies were prepared to hand over the ground required by the Infirmary for the sum of £24,500. The report recommended the acceptance of these terms, as it would give the necessary space for building without overcrowding. On this ground it is proposed to build a pavilion facing the meadows, like the other medical pavilions, and constructed to contain eighty-four beds; two pavilions running east and west, to contain sixty and forty beds, and another small pavilion to contain twelve beds. The adoption of this report was carried, and since the meeting the infirmary managers have completed the negotiations for the transference of the properties.

Edinburgh Royal Hospital for Sick Children.

The directors of this hospital have appointed Mr. John Wheeler Dowden, M.B., C.M., and Mr. Robert D. Clarkson, B.Sc., M.B., C.M., to be resident physicians for six months from May 1st.

Health of Edinburgh.

The mortality last week was 85, and the death-rate 17 per 1000. Diseases of the chest accounted for 40 deaths, and zymotic diseases for 8, of which 3 were due to whooping-cough. The intimations for the week were: typhus fever, 2; typhoid fever, 2; diphtheria, 2; scarlatina, 17; measles, 104.

Edinburgh Professional Examinations.

The second professional examination is still proceeding. Professor Greenfield has not been able to take any part in it, his place being taken by his senior assistant. The new examiners are reported to be giving satisfaction to the students.

City of Glasgow Fever Hospital, Belvidere.

The following extract from the latest monthly report to the Hospitals Committee submitted by the Physician-Superintendent, Dr. J. W. Allan, will be read with interest:—"During the winter session 1891-92 two courses of clinical instruction in Infectious Diseases were conducted, one from Oct. 24th till the Christmas holidays, the other from Jan. 16th till March 12th. In each of these courses an attempt was made to keep the classes strictly to the regulation number—viz., twenty-five each; but, as will be seen from the accompanying figures, that number was rather exceeded. The classes met on Saturday, that being the only day available for students in the winter session, by the present arrangement of medical studies. The number of students attending in a winter session is thus practically restricted to fifty. A much larger number could be undertaken if the medical curriculum were extended and modified so as to give more time and opportunity for coming to Belvidere. At each meeting it was usual to give two forms of instruction—viz: (1) a short lecture in the class room, and (2) bedside demonstrations in the wards. There was thus an attempt at a combination of systematic and clinical teaching, the former necessarily meagre from the very limited time at our disposal." The clinique was attended by sixty students during the session. The attendance was regular, and, so far as was known, not one of them contracted infectious disease from visiting the wards.

The Aberdeen University.

The medical graduation took place at Marischal College on Monday. There was quite the usual amount of noise on the part of the undergraduates, and the Principal thought it best not to deliver the usual special address to the young graduates. Twelve gentlemen were promoted to the degree of M.D., and the theses of Mr. A. R. Cushny, M.A., M.B., C.M., and Mr. James Galloway, M.A., M.B., C.M., were considered worthy of "highest honours," and that of Mr. Edgar Stevenson, M.B., C.M., of "commendation." Forty-one gentlemen received the degrees of M.B. and C.M. Mr. W. Trethowan graduated with "highest honours," and Mr. Davidson, Mr. Duncan Mackintosh, Mr. Thomas W. Ogilvie, Mr. Pirie, and Mr. James Rush graduated with "honourable distinction." The diploma in Public Health "with credit" was conferred on Mr. John T. Wilson, M.B., C.M. Twenty-three gentlemen passed the first division of the first professional examination, forty have completed the first professional, and forty-five have passed the second professional examination. Mr. Ashley Mackintosh, M.A., gained the Fife-Jamieson Memorial Gold Medal in anatomy; Mr. Peter Howie, the Keith Gold Medal for systematic and clinical surgery; Mr. Alexander Stables, the Shepherd Memorial Gold Medal for systematic and practical surgery; and Mr. W. Trethowan, the Matthews Duncan Gold Medal in obstetrics.

April 5th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Presentation to Mr. Hamilton Burke, F.R.C.S.I.

THIS gentleman, who for many years was senior medical inspector of the Local Government Board, was last week presented with a silver tea and coffee service, silver claret jug, and silver salver, from dispensary medical officers and officers of unions belonging to the province of Leinster. Miss Rita Burke was also presented with a bracelet. The address, which was illuminated, having been read, a suitable reply was given by Mr. Burke, who afterwards entertained the deputation at luncheon. The salver bears an inscription to the effect that it was presented with a silver tea and coffee service to Mr. Burke, on his retirement from the office of medical inspector, Local Government Board, by his many friends among the dispensary, medical, and other principal union officers of the province of Leinster, in appreciation of his invariable kindness, consideration, and courtesy to them during the many years of his official charge of that extensive district.

Dinner to Surgeon-Major-General J. Sinclair.

A farewell dinner was given recently at the Shelbourne Hotel by officers of the Medical Staff in Ireland on the active and retired list to Surgeon-Major-General J. Sinclair, who occupied the post of Principal Medical Officer in Ireland until March 28th last, when he was placed on the retired list. Surgeon-Colonel Collis succeeds Surgeon-General Sinclair as Principal Medical Officer in Ireland.

Health of Ireland in 1891.

The total births registered in Ireland during the year 1891 amounted to 107,883, or 23·0 per 1000, and the total number of deaths was 86 053, or 18·4 per 1000. Of these 86,053 deaths, 4406—a number equal to 0·9 per 1000 living—were caused by one or other of the principal zymotic diseases.

Royal College of Surgeons.

It is intended to present the President, Mr. Croly, with his portrait on the occasion of his retirement, on the completion of his second year as President of the College. Dr. Edward Hamilton has issued cards as a candidate for the presidency of the College for 1892 and 1893.

Proposed Hospital for Consumption.

Dublin has naturally a damp climate, and it has occurred to many that locating a hospital which is expected to be a curative institution in or near Dublin would be a great mistake. There are counties, it is urged, in Ireland where the winters are much milder than the county Dublin, and where the temperature is more equable. There is one place peculiarly situated, and for which it is claimed that at the present season of the year it is the warmest district in the United Kingdom, and the place, above all others, where an invalid may with comparative comfort and safety sojourn. This is Glengarriff, styled by a recent author "The Madeira" of Ireland, which is situated on the south-west Irish coast. It lies in a vale, protected on all sides from the cold and sharp winds by lofty mountains, the only wind that has free access to it being from the south. As a winter resort, the author above referred to says that Glengarriff has no equal in Ireland. It has a mean winter temperature of 45°, and its mean annual temperature is 52°, a higher mean annual temperature than the most noted of the English winter health resorts. In the months of December, January, February, March, and April the climate at Glengarriff is exceptionally mild, and there is an unusually large amount of daily sunshine, permitting of free exercise in the open air, which to the invalid at that season of the year is a great and manifest advantage. There are difficulties, no doubt, in the way; but if a hospital for phthisis is to be established, why not erect it in the most suitable position that can be obtained, either in Kerry or elsewhere?

Dublin Sanitary Association.

The report of the council for the past year again protests against the large number of private slaughterhouses in the city, as being a source of danger to the health of the citizens. The annual death-rate in Dublin last year was 25·5 per 1000 as compared with 26 3 the previous year. In the city there was a reduction from 29·0 to 28·5, while in the suburbs there was a reduction from 19·9 to 18·5, which is an exceptionally low rate. It is satisfactory to note that in spite of the influenza epidemic, which in both of the last two years considerably swelled the number of deaths from diseases of the respiratory organs, the general death-rate both in the city and suburbs for 1891 was below the average of the last ten years, and that the typhoid epidemic which attracted so much public attention last autumn did not eventuate in any considerable increase of the total deaths from fever (202), which were less than in any of the last ten years, except in 1886 and 1887, when the deaths from fevers of all kinds were only 192 and 193 respectively. The most striking feature in the returns for last year is the extraordinarily small number of deaths from measles and scarlet fever, which together caused only 9 deaths. The report being adopted, the president read an address on the subject of preventable diseases, and the proceedings terminated.

It is proposed to erect a memorial window in Kildare Cathedral to the memory of the late Mr. S. Chaplin, F.R.C.S.I.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Horse-racing and Charity.

It is only a long residence in this city that enables the student of human nature to appreciate the important part taken by horse-racing in the thoughts of a large section of our population. *Garçons de café*, shop boys, small tradesmen, and clerks, these are the individuals who, with marvellous recklessness, risk again and again their small earnings on the chances of a "good tip." The powers that be, accepting the gaming propensities of the populace as an unavoidable nuisance, have very wisely taken measures to divert some of the invested cash into charitable channels. To this intent, it is ordained that a certain percentage of the money staked shall revert to the Assistance Publique, and that the charities of the country in general gain considerably by this arrangement is proved by the fact that no less a sum than 800,000 francs has just been allotted to those judged the most deserving or necessitous. Of this large sum, 700,000 francs have been set apart for the purpose of constructing a hospital at Blanchefasse (Seine et-Oise) for the consumptives of Paris. The architectural details of this projected building will be a reflex of recent advances made in the knowledge of the etiology and therapeutics of King Phthisis. The surplus of the betting fund will be devoted to such laudable purposes as the installation of a disinfecting stove at the Rennes hospital, the support of the Retreat for the Aged Poor at Salarre in the department of Ariège, and to the furtherance of the revaccination campaign under the auspices of the Paris Academy of Medicine. "'Tis an ill wind that blows nobody any good," and we once more see how human folly can be turned to good account. Might not a similar arrangement be adopted by *ces gens pratiques par excellence, Messieurs les Anglais?* The British poor would assuredly have no objection.

Military Hospital Gossip.

While on the subject of hospital construction I may mention that it has been decided by the War Office to suppress the existing urban military hospitals St. Martin and Gros-Caillou, and to replace them by a single new establishment, which shall be situated outside Paris. The situation has not yet been selected; but it is intended to provide for the easy conveyance of patients from the different barracks of Paris to the new hospital by the construction of a special tramway line. The present clumsy, jolting, and slow system of transport by ambulance waggons will thus be superseded, to the great advantage of individual sufferers and of the service in general. The new hospital will contain 600 beds. This centralisation of the military sick will entail a loss of about twenty beds, but it is thought that the addition of a few beds to the Val-de-Grâce hospital and the better utilisation of the regimental infirmaries will more than make good this deficiency. The nursing at military hospitals was, during the imperial *régime* and at the suggestion of the Empress Eugénie, entrusted to *religieuses*. An arrangement was, for this purpose, entered into between the Government and the different religious orders, such as the St. Vincent-de-Paul, and it appears that this treaty will shortly lapse. Meanwhile, the work of ousting the religious element from hospital nursing staffs is being extended to military establishments. Of the forty sisters placed by the Empress at the Val-de-Grâce hospital, there now only remain twenty. Despite the protests of such journals as *Le Soleil* and *Le Gaulois*, it is evident that the picturesque *sœur* is doomed to disappear at no very distant date from the wards of French hospitals, both civil and military. The status of officers under treatment in a military hospital has hitherto been a matter of doubt, it being a moot point whether the fact of his occupying a bed in such an establishment deprives him temporarily of his privileges as an officer. The question has recently been settled so far as the French army is concerned. The circumstances leading to the decision are these: An officer under treatment at Val-de-Grâce Hospital put a hospital orderly under arrest for having neglected to address him as "*Mon lieutenant.*" The *médecin en chef* promptly cancelled the punishment, whereupon the wrathful officer appealed, first to the military governor of Paris, who upheld the action of the chief surgeon, and finally to the Minister of War. The Minister referred the matter to a committee, who took the same view as the governor of Paris. The reasons upon which the decision is based are given *in extenso*. Thus it is stated that the dress worn by officers while in hospital is not distinctive, and orderlies are consequently not supposed to recognise the grade of such patients. It has also, in the interests of the patients themselves, been enacted that orderlies are not to obey the orders of officer patients. Were it not so, such patients might compel *infirmiers* to supply them with forbidden articles like alcohol, tobacco, &c. The French army surgeon can now breathe freely; his position is distinctly defined; he is supreme in his own wards. This is as it should be.

A Great Scandal at the Faculty of Medicine.

There is held periodically at the Paris Faculty of Medicine a competitive examination for the filling up of any vacancies that may occur in the list of *professeurs-agrégés* in medicine or surgery or obstetrics at the metropolitan and provincial faculties. The examining board is composed of professors of the Paris and provincial faculties, the president nominated this year by the Ministry of Public Instruction for the examination in medicine being Professor Bouchard. When the result of this very difficult and long competition was announced a fortnight ago the absence of certain well-known names from the list of successful candidates was much commented on, and charges of favouritism and infringements of regulations in the conduct of the examination were boldly formulated both in the lay and professional press. The choice of the professors composing the Board of Examiners lies with the president of the board, himself nominated as above mentioned by the Minister of Public Instruction. A general charge is made that the discretionary power thus conferred on the president is taken advantage of in order to form a jury whose sympathies will naturally incline towards any candidates favoured by the president. It is further pointed out that the choice of a president at this year's *concours* was particularly unfortunate, seeing that Professor Bouchard, without having the title, exercises the functions of the technically suppressed post of inspector-general of faculties and schools of medicine. The irregularity alleged to have occurred in the conduct of the examination consists in this—that it was postponed for twenty-four hours pending the recovery from indisposition of Professor Sée, a member of the jury. When M. Germain Sée had recovered he could only attend during three days, and the proceedings were continued without filling up the vacancy caused by his definite retirement, which constituted yet another irregularity. Of the five successful candidates for the Paris faculty it is said that three are pupils of M. Bouchard, that three of the five are not hospital physicians, and have published no particularly important works, and, finally, that three out of the five unsuccessful candidates are not only hospital physicians, but are well known for their valuable contributions to medical science. For these various reasons the unsuccessful competitors have sent a petition to the Minister praying him to annul the choice of the examiners. That their contention merits consideration is probable from the fact that no less a personage than Professor Cornil presented the discontented phalanx to M. Lesage, Avocat au Conseil d'État, who is to champion their cause.

Operative Treatment of Spina Bifida.

An instructive paper on the above subject was read by M. Monod at a meeting of the Société de Chirurgie, held on March 16th, the *mémoire* being based upon the report of a case successfully operated on by M. Walther. The patient was a new-born infant affected with a voluminous spina bifida, which reached from the first sacral vertebra to within 1 c. of the anus, its length being 12 c. Half-way down from its base the cutaneous covering was suddenly replaced by a delicate transparent membrane, which the slightest excess of tension would have easily ruptured. Four hours after birth M. Walther performed the following operation:—After a preliminary tapping, which gave rise to 220 grammes of a limpid fluid, two lateral flaps of skin were detached from the surface of the sac, which, after being laid open, was itself dissected as far as the edges of the vertebral orifice (this was only 2 millimetres wide), and resected after being ligatured with silk. The flaps were then reunited over the pedicle, a salol dressing, with a thick collodion coating over all, completing the operation. The sutures were removed six days later,

Digitized by Google

leaving a wound completely cicatrised. A fortnight after the operation the child was exhibited. The cicatrix was then firm; no impulse could be detected during efforts, nor could any motor or sensory change in the lower extremities be discovered. Notwithstanding the favourable features presented by this case—viz., its situation, absence of cord and nerves from the sac, narrowness of the orifice of communication with the vertebral canal—M. Monod, in his admirable *résumé* of the results yielded by the divers treatments practised for the relief of this congenital condition, deems it worthy of record with the thirty equally successful cases already published by French and other surgeons, amongst the English being Mayo Robson, Sinclair, and Barton. It is only fair, however, to recall the failures that have attended this form of surgical intervention. Bellanger (Thèse de Paris, 1891) tells us that of 24 cases thus operated on, 8 died—a mortality of 33·3 per cent. This is only what one might expect, for, as M. Monod very aptly remarks, there are spinæ bifidæ and spinæ bifidæ. The varying anatomical relations of the tumour readily explain the success of the elastic ligature, of compression exercised by means of Rizzoli's forceps &c. The diagnosis of the contents of the sac being generally a matter of conjecture, we cannot help predicting that whenever sufficient skin exists over the tumour to form flaps the *méthode sanglante* will tend to become the *méthode de choix*. Even should nervous elements be found in the sac, the experience of Périer, Hildebrand, Rosenbach, Bayer, Cockburn, Picqué, and Guttenbauer shows that they can be dissected off its inner surface and pushed back into the canal without compromising the success of the operation. The radical cure can, moreover, by this means be rendered complete. Mayo Robson attempted to close the vertebral opening by transplanting a periosteal flap derived from an animal; Dollinger and Senenko brought the laminæ together by suture after having fractured them at their base; while, more recently, M. Berger succeeded in filling up the interval by grafting bone taken from a rabbit. I myself had the advantage of witnessing this operation as performed by M. Berger at the Lariboisière Hospital. Should operative measures be out of the question, M. Monod advises recourse being had to injections with Morton's solution, of which he speaks very highly.

(FROM OUR OWN CORRESPONDENT.)

The Death of the Sleeping Miner.

THE Silesian miner, Johann Latus, who slept from Sept. 17th, 1891, till Jan. 30th, 1892, died the other day. The necropsy showed that death was simply the natural end of a state of profound exhaustion caused by the morbid conditions consequent on lying motionless so long. The chief of these was the gangrenous state of the lungs, due perhaps to the accumulation of blood in them during the long sleep, but perhaps also to the passing of portions of food and drink into them, owing to the weakness of the patient after awaking. Except slight meningitis of very recent date the brain was perfectly intact. Deposits of a nature not yet ascertained were found, which surrounded the substance of the spinal cord. These deposits will be microscopically examined, but their presence on the cord is believed to be a sufficient reason for the phenomena of this remarkable case. They were found round the motor nerves only, which explains why the skin during the long sleep was sensitive even to slight irritations, whereas the limbs lay stiff and motionless, and could be bent only by the exertion of considerable force.

The Langenbeck House.

The Langenbeck House is to be opened on the occasion of the twenty-first congress of the German Surgical Society, to be held here from the 8th to the 12th of next June. An exhibition of surgical instruments and apparatus is to be held in connexion with this inauguration and with the congress, and intending exhibitors should apply to Dr. A. Koehler, Luisenstrasse 48, or to Dr. B. Schimmelbusch, Ziegelstrasse 5-9, before May 1st. Langenbeck's eldest daughter (the Countess Hardenberg) has presented the House with a life-size portrait of her father, painted by Schrader.

The Removal of Rubbish.

The German Public Health Society occupied itself at its sitting last Monday with the question how the rubbish of Berlin could be better got rid of than at present. Dr. Theodor Weyl proposed some time ago that it should be burned in destructors, on the ground that this system is successfully applied in England and Belgium. Geheimerath Spinola remarked, with reference to this, that Herr Schlossky, who has to superintend the cleansing of the Berlin streets, does not think the use of Fryer's destructors suitable for Berlin, that the municipal authorities of this city, however, recognise the necessity of a change in the matter in question, and that a partial remedy is about to be applied by the establishment of a central place outside the city, to which all the rubbish will be conveyed by water. Dr. Weyl went minutely into the question whether the Berlin rubbish is fitted for being burned in destructors. The objection that English rubbish, being richer in coal, is easier to burn was met by Dr. Weyl's statement that English rubbish is quite easily burned in summer, when its coal contents are considerably less than in winter. He dwelt on the hygienic drawbacks of the system now followed here.

Professor Flückiger.

Professor Flückiger of Strasburg, who now retires into private life, has taught in the university of that city since 1873. Before his appointment there he held a professorship in the University of Berne, and also the office of a State apothecary. His writings are among the necessary helps of pharmacentists, and comprise valuable contributions to the history of pharmaceutics.

Professor Joseph Koenig.

A professorship of the Chemistry of Food and Drink has been founded at Muenster, and Dr. Joseph Koenig, who has been at the head of the Experimental Institute for Agricultural Chemistry there since 1871, has been appointed to fill it. He is the author of important writings on the subject which he is now appointed to teach.

Dr. Robert Sommer.

Dr. Robert Sommer has established himself as a private lecturer at Würzburg. He is known as a student of philosophy as well as of medicine, and has published a treatise on the origin of the mechanical school of medicine in the end of the seventeenth century. He is assistant to Professor Rieger in the University Clinic for Mental Disease in Würzburg.

Statistics.

In the week which ended on the 19th ult. 2 persons died in Berlin from erysipelas, 2 from puerperal fever, 2 from articular rheumatism, 2 from syphilis, 3 from quinsy, 4 from typhus fever, 7 from gastro-intestinal catarrh, 8 from whooping-cough, 9 from influenza, 10 from scarlatina, 12 from measles, 19 from diarrhœa with vomiting, 21 from diarrhœa, 22 from cerebral apoplexy, 23 from diphtheria, 35 from senile decrepitude, 46 from pneumonia, and 91 from pulmonary phthisis; 4 persons poisoned themselves; 14 died violent deaths, eleven of them by suicide. The mortality of Hamburg was 21; of Berlin, 21·1; of Dresden, 22·9; of Breslau, 25·5; of Munich, 29·6. Of the German cities with more than 100,000 inhabitants, Stettin had the lowest mortality (18·4), Cologne the highest (33·7).

Medical Legislation in New South Wales.

I MENTIONED in a former communication that the Ministry of which Mr. Dibbs is head had brought in a Bill to regulate the practice of medicine. This project of law has now passed the Upper House, and being a Government measure, will very likely be presented to the Legislative Assembly before the session closes. The Bill contains a preamble, twenty-eight clauses, and three schedules. It is introduced "to enable persons requiring medical or surgical advice or aid to distinguish qualified from unqualified practitioners." So runs the preamble, and the measure, if passed, will fully justify the preamble, for under its provisions all the uneducated quacks in the colony will be raised to the level of qualified practitioners. The outline of the Bill is briefly this. The present Medical Board, whose only duty is to inspect diplomas and register

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

them, without asking any questions, and who have not the power to strike even the names of dead doctors off that Register, is superseded by a Medical Council of ten persons. Five of these are nominated by the Crown and five by the Senate of the Sydney University. There is no provision for the direct representation of the profession. An official Register is established, to be in the keeping and under the control of the Council. The Council may register any diploma or degree on proof that the person submitting the diploma or degree is the person named in the papers submitted, and on further proof that the college or university from which the diploma or degree has emanated required a course of medical study of not less than four years. Schedule 2 enumerates all the colleges and universities of the United Kingdom as qualifying bodies under the Act. All practitioners at present on the Register of the colony shall on the passing of the Act become unregistered, and must apply for re-registration, with full proof of their identity and of the genuineness of their diplomas. They must also pay a fee of two guineas. This necessity for re-registration is imposed so that the Council may be able to reject a certain number of persons now registered fraudulently, and also to strike out the names of dead men. A separate folio of the Register is reserved for unqualified persons who have been in practice in the colony for five years previously to the passing of the Act, provided that within two years of that passing they pass an examination in accordance with the regulations laid down in Schedule 3. Another class to be registered on a separate folio are those unqualified men who may be able to adduce proof that they have been in continuous and reputable practice for twenty-five years immediately anterior to the Bill becoming law. The Council has the power to refuse to register or to erase from the Register the name of any person who has been struck off the list of his college or off the Register of the United Kingdom, and the Council may, by a majority of two-thirds, investigate any charge of misdemeanour, felony, or disgraceful professional conduct, and visit the offending person with temporary or permanent punishment. An appeal is allowed to the person convicted to the High Court of Justice. The Senate of the Sydney University is constituted the examining body under the Act. The privileges of a registered practitioner are that he alone is eligible for Government appointments, and none but registered persons may sign death certificates and give medical evidence. Any person advertising as treating disease, injury, or ailment must place his Christian and surname in full in a conspicuous place on the house or premises to which such advertisement refers; and if unregistered he must add, "not registered under the Medical Act, 1891." The penalty for violation of this regulation is a fine of £50, or twelve months' imprisonment. Persons guilty of false registration or of falsely using the title of doctor, physician, surgeon, &c., shall be mulcted in a similar amount. The remainder of the Bill deals with administrative details. The obvious criticism of the Bill is that it is a jumble of absurdities and altogether reactionary in its provisions. The medical profession is entirely ignored, and the hive of quacks with which the colony swarms are given an opportunity of recognition by the State. The profession throughout the colony do not appear to take the slightest interest in the matter, and it is most probable that the democratic element in the Assembly will so mutilate the Bill that its own framers will scarcely recognise it.

Typhoid Fever in Melbourne.

Typhoid fever is very prevalent just now in Melbourne. The Board of Works, which was established last year, has up to the present done nothing in the direction of carrying out the sewerage system, for dealing with which it was specially created. The want of money is the reason of its supineness. A municipal loan of £2,000,000 is being floated for the purpose of draining Melbourne and suburbs, but the loan hangs fire. Meanwhile the people die. Dr. Gresswell has been inquiring into the spread of typhoid fever amongst school children, and has made most astounding discoveries of filthy and insanitary arrangements in connexion with the State schools. After his recent investigations he asserted that from what he had seen of the want of the commonest rules of decency and hygiene amongst the Victorians the wonder was that there was not a great deal more typhoid fever.

Water Famine at Broken Hill.

The great silver mining centre Broken Hill has recently been entirely without water, and had it not been for the promptitude of the Government in having water sent by rail, disastrous consequences must have followed. As it is, business is disorganised, and some of the mines closed; typhoid fever is rife, and lead poisoning is rapidly on the increase. The quality of the water found in the neighbourhood of the town may be judged by the following analyses recently presented to the Premier of New South Wales by a deputation of residents of Broken Hill, who interviewed Mr. Dibbs on the question of starting a water scheme to supply the town with fresh water from the river Darling. Broken Hill is the mushroom city that has grown up quite recently on the silver fields, and now has a population of nearly forty thousand people, whose ordinary drinking-water has the following composition:—

Locality.	Total solidity, grains per gallon.	Chlorine, grains per gallon.	Albumen parts per million.			Lead.
			Free.	Fixed or albuminised.	Total.	
No. 3. Craven's Dam	125 grains	1·4	1·2	0·90	2·1	Trace
No. 4. Mellowship's Dam ..	70 grains	1·1	1·34	0·84	2·18	Trace
No. 5. Town Dam	50 grains	0·5	1·5	1·0	2·5	Trace

Leprosy in New South Wales.

The Premier has laid upon the table of the Assembly the report of the Board of Health on leprosy in New South Wales during the year 1891. This has been compiled by Mr. Sagar, the secretary of the Health Department. In the course of his observations he points out that at the beginning of the year named thirteen lepers were under detention at the lazaret. During the year seventeen persons were notified to the Board as suspected to have leprosy. On examination seven were found to be ill of some other disease; ten were found to have leprosy—five of them were natives of New South Wales of European descent, four were Chinese, and one was from the Island of Tanna. One of the five whites died very soon after his discovery. The number remaining under detention on Dec. 31st, 1891, was twenty-one—one native of New South Wales of English descent, and one Chinese having died during the year. Eight of them were natives of New South Wales of European descent (six males, two females), eleven were Chinese, one a Javanese, and one a Kanaka. The total number of patients admitted since 1883 (when the lazaret was established) is thirty-one—namely: Natives of New South Wales nine, of whom one has died; nineteen Chinese, of whom eight have died; one half-caste from the West Indies, who was discharged in 1885, his sores having healed; one Javanese; and one Kanaka; total, thirty-one, of whom nine have died and one could not be detained. The male lepers are lodged in the establishment specially provided for them, which was described in the report on the subject dated May, 1891. In an appendix is a full account of the important facts regarding each of the patients of European descent. A summary, having reference to local distribution of the present series, shows that two patients are known to have been in communication with cases of leprosy; that, in connexion with the histories of cases near Mudgee and in Sydney, a Chinese leper was discovered during the present year at Mudgee; he had stayed there with his father on arriving in New South Wales twelve years ago, had lived there with his father during the year that preceded his arrest, and in the interval had lived and worked as a cabinet-maker in Sydney. Two other patients resided in widely separated neighbourhoods, but still in the same north-western district, where there is constant circulation of bush hands between the isolated sheep stations; but the patients themselves met for the first time at the lazaret. Thus the small series of cases here recorded furnish some slight hint of the contagiousness of leprosy.

Feb. 28th.

THE COLLEGE OF AGRICULTURE, DOWNTON.—The rebuilding of this college, rendered necessary by the destructive fire of last year, has now been so far completed that the premises will be ready for occupation and use next term.

Obituary.

DR. HENRY TOMKINS.

LAST week we announced the death of Dr. Henry Tomkins, medical officer of health for Leicestershire. The immediate cause of death was pneumonia, following on an attack of influenza. The deceased gentleman was a Doctor of Medicine of Queen's University, Dublin, a Bachelor of Science of Victoria University, Manchester, a Member of the Royal College of Surgeons of England, and a Licentiate of the Apothecaries' Society, London. His medical studies were pursued in Queen's College, Manchester Royal Infirmary, Queen's College, Belfast, and for shorter periods in the hospitals of London, Dublin, and Paris. He was successful in obtaining various scholarships and prizes, among them the Dunville and Turner scholarships at the Victoria University. In the year 1885 he was appointed to the important post of officer of health of the borough of Leicester, at a time when there was considerable attention being paid by the Town Council to the sanitary condition of the town. From among thirty-one candidates the committee of selection chose Dr. Tomkins. So well has his arduous work been performed that at their last meeting the Lord Mayor, on behalf of the Town Council, in describing his services, said: "The Council has sustained a serious loss in the death of its medical officer of health, Dr. Tomkins—a gentleman who had held the office for several years, who had in every department of his work shown exceptional ability, who held high professional qualifications, whose manners were always most agreeable, and who never spared himself in the discharge of the various duties, often most unpleasant, which fell upon him. The borough was singularly fortunate in securing the services of a gentleman of his high attainments, and still more fortunate in being able to retain him so long, when they knew that he had many temptations to go to other spheres. His value was recognised in the profession by his having been selected by THE LANCET as Special Commissioner to visit America at a time when the medical profession were gathered there for highly important discussion. He had now passed from among them, and the Council, he was sure, would not allow an event of the kind to take place without recording its sense of the loss, and its sympathy and condolence with the widow." This is a high but not an exaggerated tribute of praise. He has done a great deal for the borough of Leicester, in improving its sanitation, in cleansing the river, in procuring cleaner houses for the people, and in mitigating the diseases once so prevalent in the town. The completion of his work Dr. Tomkins, unfortunately, has not been spared to see. But he has left behind him many landmarks of sanitary progress in the right direction. His work as borough analyst was most enthusiastically carried out, as is evidenced in his last report to the Town Council. His contributions to medical literature were well known, and the columns of THE LANCET frequently contained communications from his pen. Of a quiet and unassuming disposition, as indeed all are who are conscious of power, he rendered himself widely known among his professional brethren by a combination of talent and industry; and he earned the esteem of the inhabitants among whom he laboured for his straightforward and unflinching advocacy of physiological and hygienic truths, and his endeavour to apply these to the amelioration of the sanitary condition of his fellow-citizens.

ESQUIRE DUKES, M.R.C.S. ENG., L.S.A.

MR. DUKES was born in Old Ford in 1813. He died on March 15th at Marquess-road, Canonbury. He was educated at Merchant Taylors' School, and subsequently at St. Thomas's Hospital. His first qualification, that of the Apothecaries, dates back to 1835, and he did not take the Membership of the College till 1860. His life was uneventful, but full of service and honourable work which secured for him the gratitude of his patients and the esteem of his professional neighbours. He joined the Hunterian Society in 1857, and was one of its vice-presidents. He worked hard till 1889, when he took into partnership Dr. Dewar. He leaves a son and four daughters.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AT a quarterly meeting held on April 7th, the minutes of the ordinary meeting of the Council held on the 10th inst. were read and confirmed, with the exception of the resolution relating to the insurance of the two museums, in place of which an amended resolution of the Committee of General Purposes was accepted.

The death of Mr. Charles Hawkins, F.R.C.S., a past member of the Council, which took place on the 4th inst., was reported, and a vote of condolence with the sister, Miss Hawkins, was passed.

In pursuance of the report of the Museum Committee, the best thanks of the Council were given to Sir Arthur Douglas Brooke, Bart., for his presentation to the College of the valuable specimens of skeletons and skulls collected by his father, the late Sir Victor Brooke, Bart. The collection comprised fourteen skeletons, eighty-eight skulls, and seven crania.

The Council, having received no dissertation for the Jacksonian Prize of last year, agreed that the subject for this prize in the year 1893 be Hydrophobia. The consideration of the subject for the next Collegiate Triennial Prize was postponed.

From a report of the Laboratories Committee it appears that there are seventeen workers in the laboratories of the Colleges.

The Council, in pursuance of the notice in the summons, proceeded to the election of a member of the Court of Examiners in the vacancy occasioned by the resignation of Mr. W. M. Baker, and Mr. Howard Marsh was elected.

The President reported that, in pursuance of the provisions of the Bradshaw bequest, he had chosen Mr. Christopher Heath as the Bradshaw lecturer for the ensuing collegiate year, and that the lecture would be delivered at some convenient date in November or December, of which due notice would be given by circular to members of the Council.

The Council elected Mr. James Galloway, F.R.C.S., the Morton lecturer on Cancer and Cancerous Diseases for the ensuing collegiate year.

Mr. Jabez Thomas, M.R.C.S., Swansea, was elected a Fellow under Section 5 of the Charter of the 15th Victoria, relating to Members of twenty years' standing.

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.—The following gentlemen passed the Second Examination of the Board in the subjects indicated at a meeting of the Examiners on the 4th inst:—

Anatomy and Physiology.—Edward J. Lumb and Jeremiah S. A. Murphy, students of Yorkshire College, Leeds; George O. Rigby and William E. Tarbet, of University College, Liverpool; Thomas Salt, Edward A. B. Poole, Alex. W. Nuthall, and William P. Nicol, of Queen's College, Birmingham; William M. Willis, Edmund A. Dorrell, and Albert E. H. Pinch, of Bristol School of Medicine; Herbert J. Peel, John H. Bellamy, and Frank S. Hardy, of Sheffield School of Medicine; Albert L'Estrange Orme, of Trinity College, Dublin; Henry Roscoe, Francis J. Smith, and Francis S. Jackson, of Owens College, Manchester; William J. Woodman, of St. Mary's Hospital; William Davies, of St. Bartholomew's Hospital and Mr. Cooke's School of Anatomy and Physiology.

Anatomy only.—Walter G. Parkinson, William Archer, and William S. Dibbs, of Yorkshire College, Leeds; Henry J. Beginbotham, of Owens College, Manchester; Thomas W. W. Bovey, of Bristol School of Medicine; James R. Webb, of Melbourne University.

Physiology only.—John B. Chadwick, Alfred B. Steward, and Robert Marshall, of Owens College, Manchester; Walter M. Jackson, of University College, Liverpool.

(Six candidates were referred in both subjects; four in Anatomy only and six in Physiology only.)

Passed on the 5th inst.:—

Anatomy and Physiology.—Chas. W. Eames and Arthur P. Cummings, of Yorkshire College, Leeds; Charles Lamplough, James W. C. Barrett, Frederick G. Messiter, John C. Griffiths, Joseph Ganner, and Wm. McE. Clendinnen, of Queen's College, Birmingham; Thos. Gregory and Allen Whitfield, of Owens College, Manchester; Alfred H. Coperman, of St. Thomas's Hospital; Daniel S. Gerrish, of Bristol School of Medicine; John Wallace, of Queen's College, Belfast; Max Walthard, of Berne University; Ernest R. Rost, of St. Mary's Hospital; Francis G. Crookshank, of University College.

UNIVERSITY OF ABERDEEN.—**The following candidates have received degrees in Medicine and Surgery:—**

Degree of M.D.—Charles G. Bennett, Buckie; Eber. Chambers, London; *Arthur R. Cushny, Fochabers; James S. Dickie, Bournemouth; Robert Eatough, Brindle; Charles T. Ewart, London; *James Galloway, London; Arthur C. Hutchings, Salisbury; William Macbain, Blackburn; Archibald D. Mackinnon, Skye; Lindley M. Scott, Aberdeen; †Edgar Stevenson, Birkenhead.

* Highest Honours. † Commendation.

Degrees of M.B. and C.M.—Wm. M. Anderson, Aberdeen; Andrew Baxter, Aberdeen; Thos. Brander, Garmouth; Wm. J. Carmichael, Aberdeen; Arthur B. Dalgetty, Auchinblae; Navroji B. Darabseth, Bombay; §Andrew Davidson, Forres; Wm. R. Duguid, Buckie; Wm. J. S. Ewan, Fyvie; Duncan Finlayson, Tain; Alexander Forbes, Leochel-Cushnie; Alexander Fraser, Inverness; Thomas H. Galbraith, London; Alex. G. Gall, Melbourne; Alex. Grant, Dufftown; John W. Grant, Watten; Edward M. Griffiths, Ruthin, North Wales; Peter R. Ingram, Kildrummy; John R. Keith, Bridge of Allan; Robert E. Kerr, Bunchrew; Alex. Lamont, Ellon; John Leach, Ardersier; §Duncan D. Mackintosh, Aberdeen; William Moir, Forgue; Hugh Mowat, Banff; James Mowat, Auchnagatt; §Thos. W. Ogilvie, Aberdeen; John G. Pardoe, Littlehampton, Sussex; §Wm. R. Pirie, Aberdeen; William Ross, Fearn, Ross-shire; Wm. A. G. Russell, Orkney; §James Rust, Aberdeen; George Savege, Montrose; Charles R. Selbie, Pitcaple; Robert R. Sutter, Timaru, New Zealand; Andrew W. Thomson, Jamaica; ‡Wm. Trethowan, Victoria, Australia; Henry L. de Vos, Ceylon; James Wallace, Fearn, Ross-shire; Alfred Wilsden, Wooler, Northumberland; Robert Young, South Australia.

‡ Highest Honours. § Honourable Distinction.

George K. Gifford (Shetland) has passed the examinations for the degrees of M.B. and C.M., but will not graduate until he attains the necessary age.

Diploma in Public Health.—John T. Wilson, Glasgow (with credit).

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS IN IRELAND: CONJOINT SCHEME.—**The following candidates have passed the Preliminary Examination:—**

J. J. Adrian, N. Beck, R. Brews, A. Eades, F. Hefferman, L. Jones, G. Kennedy, M. King, J. Martin, J. Morris, G. McDonald, J. Nesbitt, T. Neville, J. O'Connor, E. O'Farrell, G. Ross, H. Sheill, W. Veming, and J. Whyte.

The following candidates have passed the Supplemental Examination in Physics:—

J. Barry, M. Cahill, D. Clarke, V. Connor, T. Cormack, E. Corselles, A. Faulkner, R. Hamilton, E. Heard, T. Martin, L. Mayston, T. Mullins, C. Odevaine, R. O'Donovan, P. O'Meara, B. Phillipson, and E. Siberry.

UNIVERSITY OF DUBLIN.—**The following prizes have been awarded for the winter session:**—*Anatomy:* Senior Division—J. H. Morton, prize; Second Year, D. F. Walker, prize. Junior Division—Robert Friel, prize. *Practice of Medicine:* M. C. Carmichael, first prize; R. H. Kennan, second prize; F. Wynne, third prize.

GREAT NORTHERN CENTRAL HOSPITAL.—**It has been decided by the committee of the hospital situate in the Holloway-road to erect the additional wing which will complete the new buildings, as a memorial to the late president of the institution, H.R.H. the Duke of Clarence and Avondale. Tenders for the work have been accepted, the cost of which, with the necessary furniture and fittings, will amount to about £30,000.**

HOSPITAL FOR WEST FIFE.—**At a special meeting of Inverkeithing Town Council on the 2nd ult., it was agreed to combine with the Burgh of Dunfermline and the Fife County Council in erecting a hospital for the treatment of infectious diseases. The terms on which the cost should be allocated have now been adjusted. It is proposed to provide from thirty to thirty-five beds, and the capital expenditure is estimated at £3000. A site at Milesmark, near Dunfermline, has been recommended.**

HASTINGS, ST. LEONARDS, AND EAST SUSSEX HOSPITAL.—**The annual report of the hospital, read at the annual meeting on the 8th ult., stated that 500 more patients had been treated than in the previous twelve months. As to the qualifications of physicians, the Rev. J. W. Tottenham moved the following resolution: "That an alteration be made in Rule 53, to the effect that after the words 'Fellow or Member of the Royal College of Physicians of London' be inserted 'Edinburgh or Dublin.'" A prolonged discussion ensued, the ultimate result being that the present rule should be maintained.**

METROPOLITAN OPEN SPACES.—**In the eighteen months during which the London County Council has maintained the gardens and churchyards handed over to it by the Metropolitan Public Gardens Association, £323 has been spent in various necessary works. There are eleven of these places, and it is estimated that £1694 will be required to put these additions into a condition similar to the other recreation grounds, if the Council decides to permanently take them over. The total acreage of parks and open spaces under the Council's control is 3121, and the cost for maintaining these last year was £56,668.**

ROYAL COLLEGE OF SURGEONS IN IRELAND: SCHOOLS OF SURGERY.—**The following is the prize list for the winter session 1891–92:**—*Descriptive Anatomy:* Junior—George E J. A. Robinson, first prize (£3 and medal); Charles Bagot Martin, second prize (£1 and certificate). Senior—Edward Joseph Moore, first prize (£3 and medal); Ernest Alexander Meeke, second prize (£1 and certificate). *Practical Anatomy:* First year—Joseph Richardson Sinton, first prize (£3 and medal); Francis Joseph Parcell, second prize (£1 and certificate). Second year—Asher Leventon, first prize (£3 and medal); Edward Joseph Moore, second prize (£1 and certificate). Third year—Hubert Rolston Sweeny, first prize (£3 and medal); Louis Francis Corbet, second prize (£1 and certificate). *Practice of Medicine:* William Taylor, first prize (£3 and medal); James Joseph O'Donnell, second prize (£1 and certificate). *Theoretical Surgery:* William Taylor, first prize (£3 and medal); Hubert Rolston Sweeny, second prize (£1 and certificate); Arthur McCann and James Jos. O'Donnell, certificates. *Midwifery:* William John Trewhella, first prize (£3 and medal); Myles D'Exeter Jordan, second prize (£1 and certificate). *Physiology:* William Ludgate Martin, first prize (£3 and medal); Edwin C. Hayes and Arthur McCann, second prize (£1 and certificate). *Chemistry:* Maurice J. Carroll and Edward W. Siberry (equal), first prize.

MEDICAL APPOINTMENT TO COUNTY COUNCIL.—Mr. T. Woods, L.R.C.P. Lond., L.R.C.S.I., has been elected an alderman of the Dorsetshire County Council.

FOOTBALL CASUALTY.—During a Rugby match between the Liverpool Banks and the Liverpool Insurance Companies, played on the 30th ult. on the Old Boy's ground, Stanley, a young man sustained a fracture of the leg and was taken to the Royal Infirmary.

THE DRAINAGE OF THE LEA VALLEY.—A Select Committee of the House of Commons, presided over by Mr. Herbert Gladstone, have passed the Bill authorising the formation of a Board of Commissioners with power to effect the drainage of the lower portions of the Lea Valley, now subject to frequently recurring floods.

GIFT TO BIRMINGHAM.—Mr. Richard Cadbury has just formally handed over to the Mayor of Birmingham his late residence, Moseley Hall, which he has partly endowed, as a convalescent home for children. There is accommodation for 150 beds. The value of the gift with the donation to the endowment fund is estimated at £30,000.

CORONERS IN BOROUGHS.—Where owing to the death of the coroner of a borough a vacancy occurs in his office, it is proposed, in a Bill introduced by Sir A. Rollit, M.P., to empower the mayor of the borough to appoint a fit person to act as temporary coroner until the vacancy is filled by the council of the borough. In such cases the temporary coroner would have the same remuneration &c. as the ordinary coroner.

OPENING OF NEW HOSPITALS IN BOMBAY.—His Excellency the Governor, who was accompanied by Lady Harris and attended by Captain Nuthall, A.D.C., on March 17th performed the ceremony of formally opening the Sir Dinshaw Maneckjee Petit Hospital for Women and Children, the Bai Motlibai Obstetric Hospital, and the Dwarkadas Lalloobhoy Dispensary for Women and Children, the three new institutions lying off the Baboola Tank-road, and in close proximity to the Sir Jamsetjee Jejeebhoy Hospital.

NORTH-WEST LONDON HOSPITAL, KENTISH TOWN-ROAD.—The past year of this institution has been specially prosperous financially. The deficiency of the funds at the opening of the year gave much anxiety. Outstanding liabilities amounted to upwards of £2700, and the current expenditure for the year of not less than £3500 had to be provided. But Baron de Hirsch headed a list of subscriptions for £1000, and Mr. John Maple gave £100 on condition that twenty donations of a similar sum were forthcoming. The offer met with ready and satisfactory responses, and the work of the hospital has suffered no curtailment, but has increased.

POPLAR HOSPITAL FOR ACCIDENTS.—The thirty-seventh annual report shows that the usefulness of the charity had been satisfactorily maintained during the past year. The twelvemonth's receipts reached £8000, the largest sum received in any one year. This result is due to the special appeals made for additional funds. To meet the requirements of the honorary surgeons and the building committee for necessary improvements, plans were prepared and subsequently accepted, involving an outlay of £6088, and the work had been commenced and should be finished by November next. The amount subscribed does not permit the committee to erect the much-needed ward for women, which would enable them to complete the buildings. The cash statement shows a balance in hand of about £910 on the general fund.

PRESENTATION.—On the occasion of the members of the Infirmary Medical Superintendents' Society dining together with numerous friends at the Inns of Court Hotel, Holborn, on the 26th ult., advantage was taken to present Dr. John Henry Bridges, the medical inspector of the Local Government Board, with a silver salver and an illuminated address, subscribed for by the whole of the medical superintendents of the Metropolitan Poor-law infirmaries, as a mark of their appreciation of his courtesy in the discharge of his duties in connexion with the infirmaries, and of regret at his approaching retirement. Dr. Bridges, in an appreciative response, concluded by expressing his regret at the prospect of his active connexion with the infirmaries ceasing, but looked forward to his moral support continuing, and he felt sure that the members of the Society might look for the cordial support of the new head of the department, Dr. Thorne Thorne.

QUEEN'S HOSPITAL, BIRMINGHAM.—The annual report, just issued, shows a large increase in 1891 of the number of patients treated, which testifies to the growing importance and value of the charity to the city in its benevolent work. A wholesome improvement appears in the subscription list. The contribution from the Hospital Saturday collection had this year amounted to £1759 9s. 10d., the largest sum yet raised by that organisation on its behalf. The sanitary condition of the hospital was highly satisfactory, and the external nursing department had proved an important and valuable auxiliary.

MEDICAL NOTES IN PARLIAMENT.

Smoke Nuisance (Metropolis) Bill.

IN the House of Lords, on Thursday, March 31st, the House went into Committee on this Bill, which, after some consideration, was reported to the House, and afterwards referred to the Standing Committee.

The Water-supply of London.

In the House of Commons, on Friday, in answer to a requisition by Sir R. Temple desiring the names of one or two influential residents in Surrey to be added to the Commission, Mr. Ritchie replied that the question of the constitution of the committee had been very carefully considered. The Government could not accede to the suggestion of his hon. friend.

Yellow Fever on Transports.

In answer to Mr. Leighton, Mr. Brodrick said two cases of yellow fever occurred during the voyage of the *Atlas* to Halifax; and since arrival one case had been sent to the hospital. The percentage of sick to strength among the white troops at St. Lucia had been fairly constant since the increase of the garrison, and it had averaged 9·9 per cent.

Fever among the Royal Horse Guards.

In the House of Lords on Thursday, the 7th inst., the Earl of Arra gave notice that he will ask the Government how many cases of typhoid fever have occurred among the officers of the Royal Horse Guards (the Blues) since August last, whether any examination has been made by the military or other medical or sanitary authorities during the past year of the barracks and quarters occupied by the Royal Horse Guards up to April 5th, 1892, and whether there is any objection to lay these reports, if any have been made, on the table o the House. The question will be addressed to the Government soon after the reassembling of the House of Lords.

Queen's College, Belfast.

In the House of Commons on Thursday Mr. Sexton asked the Chief Secretary to the Lord-Lieutenant of Ireland what steps had been taken to provide the medical students of Queen's College, Belfast, with a summer session for dissection.—Mr. Jackson replied that he did not know that any application for a summer session in anatomy had been made to the authorities of the College, but he was aware that the President did not consider such a session necessary.—Dr. Tanner asked whether the right hon. gentleman was aware that summer sessions were quite ordinary.—Mr. Jackson: Yes, sir; but not necessary.

The Colour Vision Committee.

Sir Henry Roscoe asked the President of the Board of Trade whether he could state when the report of the Colour Vision Committee, appointed at his request by the Royal Society, would be laid upon the table of the House.—Sir M. Hicks Beach replied that the Chairman of the Committee expected to be able to report to the Royal Society at the end of the present month. As soon as the report reached him (Sir M. Hicks Beach) he would lose no time in laying it on the table.

The National Vaccine Establishment.

Mr. Summers asked the President of the Local Government Board whether he was aware that the humanised lymph distributed from the National Vaccine Establishment, which was derived from various public vaccinators throughout the country, had been found, on examination, to vary greatly in quality, and, in some cases, from 60 to 70 per cent. of

Chairman of the Committee expected to be able ... Secretary at the end of the present month. ... [illegible] ... the table.

The National Vaccine Establishment.

Mr. Summers asked the President of the ... whether he was aware that the Institution ... National Vaccine Establishment, which was ... throughout the country, had been found ... the tubes had, upon microscopic examination by Mr. Farn, the official examiner of vaccine lymph, been rejected as unfit for use; and whether, in view of these facts, he would advise that no lymph should be used for public vaccination unless it had been first submitted to official microscopical examination.—Mr. Ritchie: As I very recently informed the honourable member, in reply to a question by him, the only humanised lymph distributed by the National Vaccine Establishment which is not microscopically examined is that supplied on points, and this lymph is exclusively furnished to the Department by their own officers, who themselves have carefully taken the lymph. I see no reason to advise a change in the existing arrangements as to the lymph for public vaccinations.

Scurvy among Sailors.

In reply to a question by Colonel Hill, Sir M. Hicks Beach said that returns on the subject of the health of crews of ships were presented to Parliament in 1876, 1879, and 1883. Since then there had been a great decrease in the number of outbreaks of scurvy, the number reported diminishing from 99 in 1881 to 13 in 1891. He was glad to be able to add that these outbreaks had diminished in severity as well as in number.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

Medical Diary for the ensuing Week.

Monday, April 11.

ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M., and on Tuesday, Wednesday, Friday, and Saturday at the same hour.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations daily at 10 A.M.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.

CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M.; Thursday, 2.30.

HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.

METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.

ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.

CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M., and each day in the week at the same hour.

UNIVERSITY COLLEGE HOSPITAL.—Ear and Throat Department, 9 A.M.; Thursday, 9 A.M.

MEDICAL SOCIETY OF LONDON.—8.30 P.M. Clinical Evening. Mr. Watson Cheyne: A case of Removal of the Breast treated by Thiersch's Method of Skin Grafting.—Mr. Harrison Cripps: (1) A case of Chancre of Face; (2) A case illustrating Amputation of the Penis by a Perineal Method.—Mr. Hugh Smith: A Preparation of the Parts from a case of Unreduced Dislocation of the Shoulder, with Clinical History.—Dr. T. Colcott Fox: Two cases illustrating the Development of Lupus Vulgaris from Scrofulous Glands and Scrofulous Gummata.—Dr. W. Pasteur: Pigmentation of Mucous Membrane of Mouth and Gums. Cases will also be shown by Dr. Mitchell Bruce and Mr. Sheild. Mr. Brudenell Carter will show at the commencement of the meeting an instrument for facilitating the performance of Mules's operation. By the President: (1) A Specimen of Plugging of the Duodenum from a Lamb; (2) Infective or Melanotic Freckles in Senility (portrait).

Tuesday, April 12.

KING'S COLLEGE HOSPITAL.—Operations, 2 P.M.; Fridays and Saturdays at the same hour.

GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at same hour. Ophthalmic Operations on Monday at 1.30 and Thursday at 2 P.M.

ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.

ST. MARK'S HOSPITAL.—Operations, 2 P.M.

CANCER HOSPITAL, BROMPTON.—Operations, 2 P.M.; Saturday, 2 P.M.

WESTMINSTER HOSPITAL.—Operations, 2 P.M.

WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Consultations, Monday, 2.30 P.M. Skin Department, Monday and Thursday, 9.30 A.M. Throat Department, Tuesdays and Fridays, 1.30 P.M. Electrotherapeutics, same day, 2 P.M.

THE QUEEN'S COLLEGE, BIRMINGHAM.—4 P.M. Dr. Arthur Foxwell: The Condition and Treatment of the Vascular System in Chlorosis and other Debilitated States. (Ingleby Lecture.)

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—Mr. Rickman John Godlee: A case of Ligature of the Second Part of the Left Subclavian Artery for the Cure of an Axillary Aneurysm.—Dr. George Thin: On the Symptoms and Pathology of Psilosis (Linguæ et Intestini).

Wednesday, April 13.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.

MIDDLESEX HOSPITAL.—Operations, 1.30 P.M.; Saturdays, 2 P.M. Obstetrical Operations, Thursdays, 2 P.M.

CHARING-CROSS HOSTITAL.—Operations, 3 P.M., and on Thursday and Friday at the same hour.

ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour.

LONDON HOSPITAL.—Operations, 2 P.M.; Thursday & Saturday, same hour.

ST. PETER'S HOSPITAL, COVENT-GARDEN.—Operations, 2 P.M.

SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.

GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 1.30 P.M.; Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.

ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.

CHILDREN'S HOSPITAL, GREAT ORMOND-STREET.—Operations, 9.30 A.M. Surgical Visits on Wednesday and Saturday at 9.15 A.M.

HUNTERIAN SOCIETY.—8.30 P.M. The President: A case of Acromegaly. Dr. T. Marshall: A case of Local Sweating of Face.—Dr. Jas. Galloway: A case of Morphœa undergoing Resolution.—Mr. J. Poland: A large Adeno-fibroma of the Breast.—Dr. A. T. Davies: (1) A case of Myxœdema; (2) A case of Transposition of the Viscera.

Thursday, April 14.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M. Surgical Consultations, Wednesday, 1.30 P.M. Ophthalmic Operations, Friday, 1.30 P.M.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Ear and Throat Department, 9 A.M.

Friday, April 15.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

Saturday, April 16.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; and Skin Department, 9.15 A.M.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and address of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

We cannot undertake to return MSS. not used.

A WARNING.

IT has come to our knowledge during the last few days that a preparation of a chemical nature has been advertised with the name of this journal as part of its trade title. We need hardly say that we have forbidden the use of the name of THE LANCET for the purpose indicated, and our readers will be assured that in no case has any company, firm, or individual the right, either expressed or implied, to use the name of THE LANCET, or the word "Lancet," as part of the trade title of any article, compound, or substance whatsoever.

PRISMETRY.

Mr. Dixey, the well-known optician, addresses to us a letter in which he expresses his opinion that instead of numbering prisms according to the angle of inclination of the sides, as now commonly practised, it would be well if ophthalmic surgeons would adopt the notation recommended by Dr. Maddox in his work on Prisms, in which the angle of deviation of a ray of light passing through the prism is taken as the basis. Mr. Dixey points out very justly that the present method is very unsatisfactory, in view of the different materials of which spectacle lenses are made, such as pebbles and tinted and plain glass, and that the method of numeration suggested by Dr. Maddox is much more scientific, and will certainly lead to more satisfactory results when the optician carries out the directions of the ophthalmic surgeon. In this view we are in complete accord with Mr. Dixey.

Cestrian.—1. The degree is registrable only as an additional qualification.—2. Yes.—3. Information is given in our Students' Number published in September last; or application might be made to the Secretary of the Brussels Medical Graduates' Association, Dr. Steele, 3, Hamilton-road, Ealing, W.

Dr. Fred. J. Smith.—We can, obviously, undertake the analysis of cigarette papers only in cases where there is reason to suspect their innocuousness.

J. D. F.—Messrs. Leggott and Marsh, Market-street, Bradford.

AN INTERESTING DOCUMENT.

To the Editors of THE LANCET.

SIRS,—As much has been said lately about Sir Provo Wallis, the survivor for so long of the action between the *Chesapeake* and the *Shannon*, I send you a copy of a document in my possession, which will give your readers the name of the surgeon of the *Shannon*; and as possibly someone of his descendants may be in our profession, it may interest them to know that his name is preserved along with that of Sir Provo Wallis in my collection of autographs.

"These are to certify the Directors of the Chest at Greenwich that Peter Van Loo, quality L.M., was wounded on board His Majesty's ship *Shannon* by receiving a splinter wound on the left shoulder, removing the integuments for a great extent, on the first day of June, One thousand eight hundred and thirteen, being then actually upon His Majesty's service in engagement with the United States Frigate *Chesapeake*. Aged about 21 years. Born at or near Oldenburgh, Germany.

"P. B. V. BROKE, Captain. | PROVO W. P. WALLIS, Lieutenant.
— GOUGH (?), Master. | ALEX. JACK, Surgeon."

The name of the master is, I think, Gough; but it is so indistinctly written that I cannot well make it out. Can any of your readers help me?

I am, Sirs, yours truly,

Peterborough, March 29th, 1892. W. EASBY, M.D.

PRISMATIC.

Mr. Darcy, the well known optician, addresses to us a letter to be expressed his opinion that instead of numbering spectacle glasses to the angle of inclination of the sides, as now commonly done, it would be well if ophthalmic surgeons would adopt the method recommended by Dr. Maddox in his work on Prisms, namely, the angle of deviation of a ray of light passing through the glass, as the basis. Mr. Dixey points out very justly that the present method is very unsatisfactory, in view of the different ways in which spectacle lenses are made, such as public and private glass, and that the method of numeration suggested would be much more scientific, and will certainly lead to more accurate results when the physician carries out the directions given by the surgeon. In this view we are in complete accord with Mr. Darcy.

Cornea.—1. The degree is registrable only as an additional qualification.—2. Yes.—3. Information is given in our Students' Number published in September last; or application might be made to the Secretary of the Brussels Medical Graduates' Association, 3, Hamilton road, Ealing, W.

Dr. Fred. J. Smith.—We can, obviously, undertake to do nothing of the kind.

Cigarette papers only in cases where there is reason to suspect serious inconvenience.

J. D. F.—Messrs. Leggett and Marsh, Market-street, Bolton.

AN INTERESTING DOCUMENT.

To the Editors of THE LANCET.

SIRS,—As much has been said lately about Sir Peter Van Loo, I will send you a copy of the action between the Chesapeake and the Shannon for so long of a document in my possession, which may be of interest to readers the name of the surgeon of the Shannon; and possibly some of his descendants may be in our profession, it would be well to know that his name is preserved along with that of the captain in my collection of autographs.

"These are to certify the Directors of the Chelsea Hospital that Peter Van Loo, quality L.M., was wounded on board His Majesty's ship Shannon by receiving a splinter wound on the left thigh, which has damaged the integuments for a great extent, on the first day of June, one thousand eight hundred and thirteen, being then actually in the service in engagements with the United States frigate Chesapeake. Aged about 21 years. Born at or near Gibraltar. Proved before me at Portsmouth, this 3rd day of May, 1815.

"P. B. V. BROKE, Captain. ALEX. JACK, Surgeon.
— GOUGH (?), Master.

The name of the master is, I think, Gough; but it is not quite certain that I cannot well make it out. Can any of your readers help me?

I am, Sirs, yours truly,
F. BAILY.

April, 1892.

PUBLIC ADVERTISEMENTS AND THE SHEFFIELD PUBLIC HOSPITAL.

WE are asked our opinion on the applications of candidates for the office of Honorary Surgeon in the Sheffield Public Hospital and Dispensary advertised in the *Sheffield and Rotherham Independent*. It is permitted, of course, for a candidate for such an office to lay before the governors a statement of the facts on which he grounds his claim to be appointed. But we think that the particulars of such claims should be given by circular or private communication to governors, and not in newspaper columns. The use of the latter medium has the appearance of an appeal to the public rather than to the governors of the institution.

E. R. H. (Birmingham).—1. The coroner is at liberty to order whom he pleases to make a post-mortem examination. A previous medical attendant should be informed of the arrangements for a necropsy, and invited to be present by the gentleman ordered to make it. We are not aware that the coroner has any power to forbid the presence of the medical attendant.—2. The first part of the second question does not admit of a definite reply without fuller particulars being given. The second part of the question admits only of an affirmative answer.

Rufus.—We regret we cannot supply the information, which might possibly be obtained from the firm named by our correspondent.

Mr. W. G. Percy (Brainerd, Minn.).—Almost any good dictionary will give the information.

Dr. M'Dougal (Cannes).—The paper will appear very shortly.

"'TOUTING' IN HALIFAX."

To the Editors of THE LANCET.

SIRS,—In your issue of April 2nd, under the above heading, "Fair Play" makes certain statements that are undoubtedly misleading to your readers. He says that at the Halifax Provident Dispensary no wage limit exists. Now, this is in one sense quite correct; but your correspondent omits to state that though no wage limit is fixed, yet every intending member's name goes before the committee and medical staff, who exercise their own discretion as to the eligibility of the applicant, and if in their opinion he can remunerate a private practitioner in the ordinary way, the application is not accepted. I may say the committee have already refused many such applications. As to the charge of "touting," it is, of course, impossible to conduct any co-operative system without canvassing. The Halifax Provident Dispensary, however, is not a professional organisation, but one which works on public lines, and "touting" is not a fair expression to be applied to its method. Moreover, as your correspondent must know, there are probably hundreds of dispensaries and schemes for medical aid in operation which are equally open to the complaint. Indeed, in many cases it could be made with much greater reason, since dispensaries have been established by medical men for their own benefit, and to canvassing in these cases the charge of "touting" may more fairly be applied. As to the question of remuneration of medical men, I venture to think the allusion of your correspondent is equally unfair. Our scale of charges is practically the same as that of the Leicester Dispensary (which has 35,000 members and a staff of twenty-two medical officers), and it is more favourable to medical men than the scales of many provident institutions. But it is also the fact that medical gentlemen in Halifax cater to supply the members of friendly societies with advice, attendance, and medicine at from 1*s.* 9*d.* to 2*s.* 6*d.* each per annum, whilst the Halifax Provident Dispensary charges an entrance fee and 3*s.* 6*d.* per member per annum. If space permitted, I could quote other facts, which would doubtless occasion surprise to some of your readers; but I think what I have already said will show that your correspondent's attack on our institution is both unfair and uncalled-for. I enclose you a copy of our rules, and hope you will kindly insert this letter in your next issue.

I am, Sirs, yours respectfully,
F. M. BATLEY,
April, 1892. Secretary, Halifax Provident Dispensary.

PTYALISM.

To the Editors of THE LANCET.

SIRS,—I should be glad of any suggestions as to treatment of the following case.

An old lady seventy-five years of age is the subject of a most troublesome salivation. During sleep and when awake the flow is constant. It began about twelve months ago, and has resisted all treatment by astringents, belladonna, regulation of diet, &c. All the teeth are gone, and no false ones are worn. There is, and has been, no tenderness of the salivary glands, and, except for the constant annoyance, no apparent depreciation of the general health. Appetite good, and digestive functions satisfactory.

I am, Sirs, yours faithfully,
April, 1892. M.B., C.M.

TATTOO MARKS.

To the Editors of THE LANCET.

SIRS,—Having some ordinary blue Indian ink tattoo marks on one of my hands, the result of a boyish freak, and which are more noticeable than elegant, might I ask any of your readers if they could recommend me a fairly certain mode of extirpation short of actual excision of the skin?

I am, Sirs, yours faithfully,
March 19th, 1892. M.B., C.M.

THE MALARIAL ORIGIN OF PERIODIC OPHTHALMIA OF HORSES.

DR. T. POTAPENKO, who has been in Russian cavalry regiments for several years, communicates to the *Vrach* some remarks on the periodic ophthalmia of horses which appears to be of malarial origin; for on examining the blood of affected animals he invariably found both within and without the red corpuscles micro-organisms which, from their microscopical characters and their characteristic staining, appeared to be identical with the plasmodia found in the blood in malarial fever in the human subject. These bodies were never found in the blood of horses not affected with periodic ophthalmia. In corroboration of this view Dr. Potapenko mentions that the affection generally occurred when the horses were pastured in low-lying marshy lands, wet spring and autumn being more favourable than dry seasons.

Mr. T. Greaves Walker.—We have perused the correspondence sent to us. It is gratifying to notice the obvious personal courtesy on both sides. Our correspondent has some reason to complain of the way in which the consultation was arranged without conference with himself. But we could wish that, for the sake of the patient and the avoidance of an appearance of want of professional harmony, he had met the consultant and continued in charge of the case. It is hopeless to expect perfect consideration to medical feeling, especially in complicated circumstances, and in the height of an acute illness. The action of the consultant here, as well as the interest of the patient, made it right to subordinate private feeling, at least till the case was over. Thereafter the practitioner in attendance might have expressed his dissatisfaction to the master of his patient.

Mr. Fred. J. Green.—The Beaufort leg, manufactured by Mr. Schramm, of Princes-street, Cavendish square, would probably meet the requirement of our correspondent.

B. F. will find the information he desires in our Students' Number, published Sept. 6th last.

M.R.C.S. Eng. and *M.D.* (Nice) have forgotten to enclose their cards.

Mr. P. T. Wyman.—We are unable to entertain the proposal.

ALLEGED OFFICIOUSNESS OF A MEDICAL OFFICER OF HEALTH.

To the Editors of THE LANCET.

SIRS,—Would you kindly give publicity to the following facts in your next issue?

On the 28th ult. I was called to see a patient, and, diagnosing the case as one of diphtheria, I duly notified it as such. To my astonishment, on paying my usual visit on the 2nd inst., I found that the medical officer of health had been to the house, examined the patient, and gratuitously expressed his opinion to the relatives that there were no symptoms of diphtheria, and that the patient had not had, and was not suffering from, that disease. On meeting the medical officer of health an hour or two later I referred to the circumstance, only to be further nonplussed by his assertion that "he had only done his duty." He then turned and left me while I was still speaking to him. On the 3rd inst. I had the independent opinion (after a careful examination of the case) of a medical practitioner of standing and experience, who verified my diagnosis, and expressed his willingness to give further testimony, if need be, to its accuracy. This gentleman found the following symptoms:—Two patches of diphtheritic membrane and excoriations in the throat left by sloughing, enlargement of glands in cervical region, and partial paralysis of soft palate with the resulting nasal voice.

Now, Sirs, I would wish you or some member of the profession to let me know what a medical officer of health's duties are. Courtesy and tact surely are essential, whereas interference with a medical man's patients and criticism of his diagnosis seem to contravene both. Have instances such as the above been brought under the notice of the Local Government Board, and if so, with what result?

I am, Sirs, yours faithfully,
GEO. MCM. BROWN, M.B., C.M.Edin.

Tunstall, Staffs., April 4th, 1892.

*** If the above statement, which is of course *ex parte*, is correct, the interference of the medical officer of health was most reprehensible. Such action would paralyse the whole notification system, which throws on the medical attendant the responsibility of the diagnosis. No medical officer of health will, on reflection, undertake to act as a sort of detective to a practitioner in matters of diagnosis.—ED. L.

"ORIGINAL WORK AND GENERAL PRACTICE."

To the Editors of THE LANCET.

SIRS,—In the direction of original work suggested by your correspondent, I would propose that post-mortem rooms of the general hospitals should be understood to be accessible to general practitioners. How greatly this would help to increase our facilities for observation and directly bear on our practice is obvious, especially in these days, when coroners often limit post-mortem examinations to an extent prejudicial to the public safety, as well as to the highest interests of the medical profession.

I am, Sirs, yours truly,
April, 1892. ANOTHER GENERAL PRACTITIONER.

Digitized by Google

OPHTHALMIC CASE-BOOK.

WE have received a specimen page of a case-book for ophthalmic cases in general practice, printed for Dr. A. Maude, Westerham, by Messrs. Hooker and Sons, Westerham. It presents no particularly new feature, but will prove useful to ophthalmic surgeons.

Candidate.—Jervis on the Office and Duties of Coroners, of which several editions have appeared, published by Stevens and Sons, Chancery-lane.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

COMMUNICATIONS, LETTERS, &c., have been received from—Dr. J. W. Allan, Glasgow; Lieut.-Col. Allsopp, London; Messrs. Anderson and Co., London; Mr. J. M. Atkinson, Hong Kong; Messrs. Boulton and Paul, Norwich; Dr. G. McM. Brown, Tunstall; Messrs. Burgoyne and Co., London; Mr. T. B. Browne, London; Messrs. Battley and Watts, London; Mr. Butlin, London; Dr. Berslay, Esher; Mr. Brice, Bridgwater; Mr. Barwell, London; Dr. Bateman, London; Mr. W. H. Brown, Leeds; Mr. Birchall, Liverpool; Mr. Barford, Wokingham; Mr. Batley, Halifax; Dr. G. Carpenter, London; Dr. Coghill, Birmingham; Dr. Moss, Congleton; Dr. J. Carroll, Ilkeston; Mr. A. Cooper, London; Miss Crick, Willerby; Mr. Clutton, London; Dr. Chapman, Toronto; Mr. E. T. Collins, London; Sir W. Dalby, London; Mr. A. Duke, Dublin; Mr. Dauber, Liverpool; Mr. Daniels, Llanelly; Dr. E. Davies, Wrexham; Dr. Denholm, Manchester; Dr. W. Downie, Glasgow; Messrs. Debenham, Tewson, and Co., Cheapside; Mr. Ellis, Bishop Auckland; Mr. Earle, Netley; Mr. J. D. Farquharson, Newcastle; Mr. Frost, London; Herr Fuchs, Kissingen; Messrs. The Publisher cannot hold himself responsible for the return of testimonials &c. sent to the office in reply to advertisements; copies only should be forwarded.

NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post Offices letters addressed to initials only.

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

Terms for Serial Insertions may be obtained of the Publisher, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 66, Rue Caumartin, Paris.

Lumleian Lectures

ON

CERTAIN POINTS IN THE ETIOLOGY OF DISEASE.

Delivered at the Royal College of Physicians on March 31st and April 5th and 7th, 1892,

BY P. H. PYE-SMITH, M.D., F.R.S.

LECTURE I.

IN asking the attention of my audience to certain points in the etiology of disease, I would begin by submitting that the existence of disease in general needs no further explanation than the existence of life. Disease is as natural, as physiological, as health. No living thing is immortal, and life is a constant struggle against surrounding forces, in which each individual organism succumbs after a while, by handing on its life to its successor when it has ensured the victory of the race. Pathology is only a chapter of physiology, which for convenience we have separated from the rest. We call disease that which brings us discomfort, and then look upon every disease as abnormal, obtrusive, unkindly; but if we knew it, the highest temperature of fever is as strictly in accordance with the laws of animal thermogenesis and thermolysis as the slight diurnal oscillations of health; and the excessive secretion of the kidneys in diabetes is as much a part of the system of nature as the moderate increase produced by a cold east wind in a healthy man. The processes of degeneration and decay which lead to death should be regarded as correlative with those of growth and development which follow birth. It is as natural for the old man to shrink in bulk and droop in stature, for his permanent cartilages to ossify, his hearing to grow dull and his memory weak, as for the child to grow, for his bones to set, and his mind to develop.

It has long been known that human beings are liable to be the hosts of parasitic beings less highly organised, but living, growing, and reproducing like ourselves; and in recent times we have learnt that, in addition to the diseases produced by the presence of animal parasites, another large group is due to the invasion of countless hordes of minute parasitic plants, but to regard filariæ and bacilli as merely "causes of disease" in man is to take too narrow, too human a view. Every kind of beast, and bird, and fish, and many of the lower classes, are known habitually to harbour parasites. In the majority of cases this is without injury to the host; indeed, if the parasites were invariably destructive the victory of the individual would prove destructive to the race, since, although a host can live without a parasite, the parasite cannot live without his host. The fact is that if we call "disease" whatever is abnormal, then the "pathological" condition is to be free from parasites. The bare and inhospitable state in which the most civilised of mankind keep their bodies is only maintained by ceaseless care and vigilance; as soon as these are intermitted, numberless evicted tenants resume their natural right of domicile. The immense majority of our fellow-men, in the past and in the present, have been and are the contented hosts of a dependent fauna, which finds as natural and unblamed a habitat on or in the human body as birds in the air or fishes in the sea. From the point of view of the tænia, the trichina, or the pediculus, man is in general part of its environment, and in particular its homestead and its barn, while sanitary, economical, and pathological questions, from the parasitic point of view, refer, not to the host, but to the guest.

Let us, then, for this occasion look upon diseases not as unnatural, lawless, heterogeneous, abnormal, revolutionary, but as parts of the vast order of creation. They are not to be "explained" by any single all-mastering principle of physical evil. The various ancient systems of pathology which pretended to discover a common origin of disease are all outworn, dead, or dying, as obsolete as the correlative systems of therapeutics which pretended to deal with disease as a whole by some universal antagonistic principle. Like is not cured by like, nor contraries by contraries. The true physician is not guided by fallacious general hypotheses, but by individual insight and experience, for, as the greatest of philosophers taught, *ἰατρεύει καθ' ἕκαστα*. Let us study etiology as the natural history of diseases, the circumstances in which they arise, and the complicated conditions on which they depend, as necessary, sometimes inevitable, results of the construction and the working of the bodily machine. The practical, therapeutical side of medicine is ever with us; common humanity and the peculiar interest that each separate case excites prevent any danger of our maintaining a philosophical tolerance of disease. What we are most apt to forget is its scientific side, and to this it is that I invite your attention, not to the *seats* and *nature* of diseases, but to their *causes*—or rather, I would say, their natural beginnings—the circumstances in which they occur.

It is certain that by a study of the etiology of diseases we ultimately advance the practice of our art; for rational treatment depends on diagnosis, and diagnosis rests upon pathology, and pathology in its widest sense includes not only the anatomy, but the physiology of diseases—not only their "seats," but their "causes." Moreover, if inquiry into the origin and conditions of disease helps treatment, it is indispensable for the still better art of prevention. That depends entirely upon the extent of our knowledge of etiology; and I venture to believe that more human suffering has been relieved and more lives have been saved by the studies in natural history which have taught us the origin of infectious fevers, of scurvy and lead colic, of erysipelas and pyæmia, than by the best results of pharmacology. We still keep in memory the names of Paracelsus and Glauber, the Marchioness of Chinchon, Dr. Dover, and Mr. Plummer; but who would compare these twinkling asteroids to the splendour that surrounds the names of Edward Jenner, of Pasteur, and of Lister?

I. Let us first consider whether it is possible to classify and appreciate the several causes, external or internal, which alter or modify the ordinary working of the human machine, in such a manner as to cause pain or discomfort, to incapacitate any of its ordinary functions, or to lead to a cessation of the entire mechanism. The human body, like that of all the Metazoa, is an aggregate of more or less independent living particles; not only in the ascent from the simplest to the more complex plants and animals, but also in the development of each individual, we start with the single nucleated mass of protoplasm. Each living cell, like the organism of which it forms an element, can feed, digest and assimilate, can breathe and excrete, can be irritated, and can move. In this microcosm "nature's self untwisted lies, into its first complexities"; and, when thus unravelled, the problems of life, which we vainly thought to solve, when we understood the mechanism of circulation and secretion and movement, are seen stripped of such secondary additions, reduced to their naked simplicity, and more insoluble than ever. But if the life of a single cell be the life of the whole organism in miniature, so will be its death and the processes which lead thereto. What are the external agents which can injure or derange the ordinary functions of the cell? They may be thus stated: (1) Mechanical injuries; (2) electrical changes; (3) extremes of heat or cold; (4) chemical agents. All these, which in moderate degree act as stimuli, when more powerful become destructive. In addition, the living cell may be (*a*) starved for want of food; (*b*) stifled for want of oxygen; or (*c*) poisoned by its own excreta. If none of these accidents befall it, yet its life is limited; for, after giving birth to a new generation, the impulse which gave it being gradually weakens, until its inscrutable molecular construction and the functions which that construction make possible come together to an end. We see essentially the same disturbing forces in their action on the entire organism. Diseases may be caused by mechanical injury. To this group belong what used to be distinguished as surgical diseases, and, above all, traumatic inflammation, the reaction of the injured tissues. We may also regard as traumatic the effects of concretions, such as gall-stones and urinary calculi; their formation is a separate event to be explained on chemical grounds, the disease is not the foreign body thus formed, but the effect of its presence upon the living tissues with which it is in contact. The effects of poisons come next, but although they agree in their action being chemical, it is probable that this is their only agreement. We are at

Digitized by Google

present quite ignorant of the physiological action of hydrocyanic acid upon the ganglion cells of the bulb, of antifebrin upon those of the thermotaxic centres, and of strychnia on those of the reflex mechanism in the cord, as ignorant as when the candidate for the doctorate in Molière explained the properties of opium as due to a *virtus dormitiva cujus est natura sensus assoupire*. Nothing is positively known of electrical or magnetic changes, or of the air, the earth, or the body itself, in producing disease. May we not add that, if we except such definite effects as can be produced in the moist chamber (for example, stimulation and electrotonus), the therapeutical effects of electricity, whether statical, galvanic, or faradaic, are equally uncertain? Our knowledge of diseases caused by chemical agents is much more extensive and exact. The effects of prolonged administration, in minute doses, of metals, such as mercury, lead, arsenic, and silver, are well ascertained. The discovery of the true cause of Devonshire colic by Sir George Baker is a classical instance of etiology by inductive reasoning. Moreover, what was always a more or less probable conjecture has now been proved in certain cases to be a fact—namely, that the effects of the most numerous and destructive parasites are due to chemical poisons, which they either excrete or manufacture from the normal proteids of the body. The important paper of MM. Roux and Yersin, which appeared in the Annales de l'Institut Pasteur for 1888, proved this by direct experiment in the case of diphtheria. Of heat and cold the direct effects as we see them on the external surface are readily understood. One or two considerations, however, perhaps deserve mention here. One is the remarkable difference between the effects which the same degree of heat or cold will produce upon different skins. We have always the "irritabile" to consider as well as the "irritans." Another is the remarkable effect of habit upon living tissues as well as organisms, upon epithelium and glands as well as on the nervous system; and habit tells in two ways, by inuring tissues to bear without reaction what at first was a powerful irritant, and again in continuing the effect of an irritant which has passed away. So that chronic eczema will follow brief exposure to the sun, and chronic bronchitis may result from a single chill.

A much more abstruse effect of cold is indirect. This acts upon internal organs which are far too deep to have their temperature altered by direct external cause. How far is the popular, and we may add, medical belief, justified, that common catarrhal laryngitis and bronchitis, pleurisy and pneumonia, inflammations of the stomach and bowels, the kidneys and liver, and even the spinal cord, are due to external cold? If we try to define our current explanation of this process, we might, in the first place, suppose that cold acts directly upon the nearest underlying important organ. Some apparent cases in support of this view do not really apply; for instance, a cold wind even without the help of dust may produce injection of the conjunctivæ, but this is a direct and immediate application of cold to the organ, just as cold water or cold air acts upon the exposed skin and produces a slight dermatitis. Nor is the undoubted production of facial paralysis a case in point, for there some impression is directly made upon the periphery, perhaps the muscular end-plates of the portio dura; degeneration follows, but there is no evidence of neuritis. Again, sore-throat and bronchitis following exposure to a dry cold air are only fresh examples of cold acting as a direct local irritant. Both affections are readily produced in many persons by talking out of doors, or by the habit of breathing through the mouth, a habit which often forms part of an unlucky circle, since it is caused or kept up by chronic tonsillitis (including the pharyngeal tonsil) obstructing the entrance to the posterior nares, or by swelling of the Schneiderian membrane from coryza obstructing the anterior entrance. But do we find that bronchitis, pneumonia, or pleurisy follows the application of cold to the chest, and that enteritis or peritonitis is produced by cold on the abdomen, or nephritis by cold upon the loins? Such is the popular, perhaps we may say the common, medical belief; but is there adequate evidence of its truth? The trunk is so well covered in cold and temperate climates, that it has scarcely any chance of being chilled except by the clothes being wet through. Granting that this is a cause of acute illness, is it not as often followed by rheumatic synovitis of the extremities as by pleurisy or pneumonia? Is it not much oftener followed by coryza, sore-throat, and cough? Is it ever followed by peritonitis? There is a belief, not without foundation, that acute myelitis is often occasioned by working in water; but in all the cases of the kind I have seen the wet and cold have affected the lower extremities, certainly not the spine. No one can suppose that cold applied to the surface could possibly produce by direct conduction a local fall of temperature in organs so deeply placed as the spinal cord and the kidneys; but it is imagined that some reflex motor or trophic influence is excited, a hypothesis analogous to that which is used to explain the employment of blisters and other counter-irritants to relieve deep-seated inflammation. The evidence for such an action appears to be inadequate; the vascular communication between the parietal and visceral pleura, the lumbar and renal arteries, is but small and irregular. We have no evidence of the existence of a nervous relation of the kind supposed, and there are, I believe, no adequate clinical facts to support the hypothesis. On the contrary, many facts are against it, as the impunity with which we place ice-bags upon the head, the thorax, and, even in cases of intestinal hæmorrhage, upon the abdomen. This treatment never produces inflammation of the lungs, the brain, or the bowels. Then it is held by many good physicians that ice applied to the chest can not only check pulmonary hæmorrhage, which I confess I doubt, but also pulmonary inflammation, which I venture to disbelieve. It will scarcely, at all events, be held by the same physician that pneumonia is both caused and cured by cold applied to the chest. We seem thus to be driven to the belief that cold applied to the surface of the body has no local results beyond the effect upon the skin; that a person may be exposed to severe and long-continued cold, causing acute suffering and even local lesions, like frost-bite, without any internal inflammation. On the other hand, we often seem to "catch heat" rather than cold in crowded rooms and overwarmed houses. The mischief seems to be, not the cold, but the chill, a sudden impression which we sometimes feel when exposed to a draught on going out of a hot room in winter, or on sitting, after profuse perspiration, in summer—an impression which we sometimes feel and sometimes do not. This chill is accompanied by a rigor, often represented by nothing but a slight shiver, or by a convulsion, in the shape of a sneeze; we feel at once that the mischief has been done, and a catarrh or some internal inflammation follows.[1] What the effect will be does not appear to depend upon the locality or the severity of the chill. In most persons in this country and in temperate Europe and America, a coryza with sore-throat, followed by a slight catarrhal bronchitis, is by far the most common result; but in many persons, especially in the summer months, precisely the same kind of exposure of the face or head, which causes a common cold, will produce diarrhœa and other symptoms of catarrhal colitis, local pain, with irregular peristalsis and discharge of mucus, with furred tongue, loss of appetite, and slight rise of temperature; while in India, China, and the Southern States of America a precisely similar chill produces an attack of ague. Does the same "chill" sometimes cause rheumatic fever, pneumonia, acute Bright's disease, pleurisy, or acute myelitis? The evidence, though far less convincing than in the three cases before mentioned, seems too strong to be set aside; but we must admit that each of these effects is comparatively rare, that each of the acute inflammations enumerated frequently occur without exposure to cold or wet and without any premonitory chill, and that, even granting the general etiology in question, we cannot pretend to say why the same cause should in one case produce rheumatic synovitis, in another pneumonia, and in a third acute nephritis.

Of contagion as a cause of disease I must say but little, partly because the subject is so vast, partly be-

[1] We cannot, I think, accept the negative position proposed by Dr. Ransom of Nottingham in denying that exposure to cold is the cause even of a cold in the head. Even if we put aside the universal popular belief as to an extremely common malady, to which all civilised languages bear witness; if we put aside the prevalent medical opinion, which is unbiased by any of the theories which have dominated our schools—we cannot explain away the direct experiments which are constantly being made in this particular. A cold in the head, though often and in many people accompanied by true fever, and running a tolerably definite course, is in others, or in the same patient at another time, a mere local inflammation. It is notoriously more common in winter than in summer; it can usually be traced to a definite exposure to cold, and does not come on without such exposure; it can be checked and aborted if, when the chill is felt, warmth is at once restored, and, even when established, its symptoms can be entirely removed for a time by a hot bath, or can be quickly, safely, and pleasantly cured if the patient will submit to confinement to bed.

Digitized by Google

cause it has already been so ably treated, and so recently, in the Croonian and Goulstonian Lectures. I will only venture the following remarks upon this part of my subject. When the bacterial explanation of contagia is criticised (and it is well that so dominant a theory should be criticised), and when we are told, truly enough, that in very few cases have diseases been definitely and rigorously proved to depend upon the presence of a specific microphyte, and that in some of the best-known and most undoubted specific fevers none has yet been discovered—in typhus fever, to wit, and plague and small-pox and measles,—we must remember two important considerations in reply: First, it is abundantly clear that these diseases do not arise *de novo*, that they are strictly contagious and breed true; it is equally certain that they are not conveyed by gaseous emanations or liquid secretions, or by immaterial emanations. The fomites of plague and of scarlet fever convey the material contagion; that of variola can be collected, seen, and handled like so much arsenic or prussic acid. It is particulate, it multiplies indefinitely, it is preserved or it is destroyed by the agencies which affect only living matters. It is therefore a contagium vivum, and that being proved it is more likely to turn out one of the schizomycetes than a fungus, a microzoon or a living organism which cannot be referred to any group at present known. Secondly, although the complete demonstration of the bacterial nature of the disease has only been yet successful in four or five cases in man, yet the number equally so demonstrated which affect the lower animals is far greater; and, under the conditions of observation and experiment, we may perhaps rather wonder that the complete proof in the case of human diseases is present at all, than that the process of arriving at it is slow and the instances as yet few. The third observation is that the presence of microphytes, even when constant and pathogenic, does not determine the whole character of a disease. For we have such affections as tubercle, where the state of the soil is of greater consequence than the presence of the seed; we have the case of leprosy, where the bacilli, though constantly present, are in such small numbers that we cannot assign them more than initial importance in the result; we have cases of undoubtedly bacterial disorders which are neither contagious nor febrile, as lupus; and, lastly, there are bacterial diseases in which the microbe appears never to be distributed over the body, but to remain confined to the seat of inoculation, and thence to affect the distant organs by its chemical products, as diphtheria and tetanus. Theoretically, bacteria might produce injurious effect in one of the following ways: (*a*) By local mechanical irritation, in the same way as the acarus or pediculus; such irritation could only produce common reaction, and could not account for specific infection. (*b*) By mere bulk, their rapid multiplication obstructing capillaries or lymphatic paths, after the manner of an embolus. This, however, could only produce hæmorrhage, œdema, or other local disturbance, like the effects of the filaria sanguinis. (*c*) Again, since these minute plants grow and multiply after inoculation, they must consume an enormous quantity of material from the blood and lymph: hence it is conceivable that they might starve the host, like intestinal worms when in unusual numbers. (*d*) Again, they must consume oxygen, though probably the aggregate amount is only small, and they must excrete carbon dioxide, though this also would be but a fraction of that normally present in the blood. (*e*) They must excrete other materials, analogous to the urine of higher organisms, in so far as they are nitrogenous in composition, and more or less toxic in their effects on living tissues. (*f*) Lastly, they act as organic ferments, and change the properties of the animal fluids in which they grow from normal to poisonous.

Apart from the mode of action of bacteria, another point in the etiology of infective diseases is the method of their transference. Probably the virus, though discharged by many channels, has a much freer, more constant, and practically important outlet by a few or by one; and although capable of entering by many portals, finds it so much easier by one, that if we can preoccupy this, we may, for practical purposes, protect the whole organism from the invasion. Such channels of predilection would seem to be: for typhus fever, the expired air for leaving, and the inspired air for entering, the organism; for enteric fever, the fæces for exit, and drinking water contaminated by sewage for entrance; for scarlatina, the epidermis and the urine for discharge, and the breath for ingress; for measles, the mucus of the inflamed air passages; for small-pox, the serum and crusts of the eruption; for mumps, the saliva of the affected glands; for cholera, the rice-water discharges; for tubercle, the dried sputum. In some cases we can, more or less certainly, point to several places of invasion; thus small-pox is perhaps most often conveyed from the inspired air to the stomata of the air vesicles, and thence by the lymph and blood throughout the body; but we know from the effects of inoculation that its contagion finds a ready entrance through the nasal mucous membrane. There is some evidence in favour of occasional invasion of enteric fever through the air and through solid food, as well as through water, and also of the conveyance of tubercular infection by milk and by meat from tuberculous cows.

There is still difference of opinion as to the precise botanical position of the microphyte known as Actinomyces; but whether it, too, belongs to the schizomycetes or to a higher group of fungi, its effects are more local and irritative, and its secondary growth follows more restricted anatomical paths than we observe in the case of ordinary infective bacteria. There is now good reason to believe that actinomycosis is not conveyed by contact from diseased animals to man, nor yet by eating the flesh of an animal affected by the disease; it is probably always derived both by men and animals from the barley or other cereals infested by the parasite.

A striking proof of the need for caution in accepting conclusions before they are proved, and the fallacy to which reasoning by analogy is liable, is afforded by the case of the etiology of Ague. A few years ago the presence of a specific microphyte was assumed, and its discovery anticipated with almost as great certainty as we now feel in the case of typhus or measles. But the researches of several eminent pathologists in this direction were either fruitless or led to unsatisfactory results. At present the evidence is exceedingly strong that malarial diseases are constantly associated with the presence in the blood discs of a contagium vivum, or, if we please to call it so, a microbe, but not a bacillus or any kind of microphyte.

The presence of a distinct species of protozoon, the organisms known as Psorosperms and Coccidia, has long been recognised in the liver of rabbits and other parts in which its effects are purely local; but recently, first in France and afterwards in this country, similar structures have been recognised in the epithelial cells of molluscum contagiosum and of certain varieties of epithelial cancer. Their etiological significance is at present doubtful, but if it be established, we shall have a new form of parasitic life, producing disease in an entirely different way from bacteria on the one hand, and from the hitherto recognised epizoa and entozoa on the other.

II. We now come to another important group of causes of diseases—namely, disturbances of one or more of the bodily functions, which are at first merely functional and do not pass the limits of normal physiology. For example, it is natural for the cardiac contractions to become more frequent under mental emotion or bodily exertion. In a healthy and vigorous man who runs a short distance without previous training, not only does the heart beat twice as rapidly as at rest, but its contractions become often irregular, while a loud, blowing murmur shows temporary tricuspid incompetence. If the exertion is repeated moderately, systematically, and in a young and healthy subject, the effects described cease, and will only reappear if he falls out of training, or if he exceeds the limit of exertion for which he is competent, or if he runs under unfavourable circumstances, as, for example, with a distended stomach, or if he attempts to repeat the feats of youth, when increase of adipose tissue, stiffness, and perhaps muscular degeneration have come with advancing years. But when violent mental emotion or excessive bodily exertion recurs too often, what was a temporary physiological variation becomes a pathological habit; the heart is readily excited to palpitation, it does so on less and less provocation, and at last without any assignable provocation at all; what was an occasional, has become an habitual, deviation from the normal. Moreover, if such functional disorders continue, they more or less surely lead to structural changes; the irritable heart becomes hypertrophied; degeneration of its tissues follows; the over-strained aorta dilates; the valves become incompetent, and the whole vascular apparatus falls into irremediable ruin. Again, a-

Digitized by Google

cold breath of air upon the face provokes a sneeze, or the presence of sulphurous acid gas in the inhaled air causes a cough, and the reflex mechanism called into action in each case is rightly claimed by the physiologist as part of the wonderful working by which the body is protected and preserved. But let the same irritants be too long or too often experienced, and, in addition to the reflex nervous mechanism, there ensue nervous changes, vaso-motor, secretory, and trophic, until a cold becomes a catarrh, and the cough becomes bronchitis. Not less frequent is the same progress of events in the digestive system. The stomach is supplied with food in too large quantities or at too short intervals, or imperfectly prepared by mastication and insalivation, or the vascular and secretory activity of the gastric mucous membrane is disturbed or completely inhibited by ill-timed cerebral excitement: the result is a physiological check to gastric digestion, and the undigested food becomes a foreign body and acts as a local irritant; the process, if long continued, leads to chronic gastritis, or perhaps to dilatation of the stomach, or the peptic glands strike work altogether, and atonic dyspepsia results. Again, inattention to natural calls may lead to nothing worse than irregular action of the bowels, but when the colon has become habituated to fæcal distension, persisting for many days, not only does its reflex peristalsis become dull and sluggish, but mechanical dilatation ensues, and we may at last have a condition of true intestinal obstruction developed from functional disturbance. Similar illustrations from the menstrual function in women are only too common.

I will only add one more. When certain articles of food, particularly spices and alcohol, are taken in more than a very moderate amount, the result is temporary vaso-motor paresis of the face; dishes compounded with curry or chilies will produce this effect in almost every case when admitted to a virgin stomach. If the degree of stimulation is moderate and the self-adjusting power of the organism good, the nervous system becomes habituated to the stimulus and the effect no longer follows: but if either of these conditions be absent, the flushing after meals becomes habitual until it is excited by wholesome food or by diluted alcohol. We then have a frequently repeated local erythema of the face which we may compare physiologically with the erythematous and urticarial eruptions produced by drugs and by special articles of diet. Recurring after every meal, this vascular dilatation at last no longer disappears in the interval, the skin and subcutaneous tissues hypertrophy, the sebaceous glands are in the condition of the submaxillary during stimulation of the sympathetic nerve, and the result is a permanent structural disease, gutta rosea—erroneously called acne rosacea,—a condition always, I believe, associated with flushing after meals, though it is often accompanied in women about the climacteric period with ovarian disorder. I need hardly repeat, what all experienced physicians recognise, that although the gastric irritant is, in most cases, some form of alcohol, yet the disease is produced not by alcohol directly, but by the gastric irritation engendered by it. Without the latter there will be no trace of gutta rosea in a patient suffering from delirium tremens or cirrhosis of the liver, while some of the worst cases of this unsightly malady occur in ladies who have never tasted strong drink and who are painfully scrupulous in their diet.

Of this important group of diseases which have their origin in physiological disturbance gradually becoming more frequent, and that end in permanent structural disease, we have always to bear in mind that, to use a homely proverb, it "takes two to make a quarrel." So it takes two to produce a disease—the blow and the reaction, the irritant and the patient. When a man complains that wholesome food disagrees with his stomach we might retort that his stomach disagrees with his food. What produces a slight and transient disturbance, or no disturbance at all, in one person, will seriously and perhaps permanently derange another; much depends upon habit and practice, and on voluntary habit and regulated practice. The muscular exertion which would produce utter exhaustion, with feeble pulse, cold sweat, complete anorexia and rejection of food, in the case of a young and healthy man who has never tried his powers, is borne with no effect but the pleasant sense of fatigue and increased digestive powers by an athlete in full training. The amount of liquor which, in the case of an unpractised drinker, would simulate mania, paralysis, or coma, will scarcely dull the senses of a practised toper. The few whiffs of tobacco which produce vomiting and something like collapse in a schoolboy, have no effect whatever when, by reason of use, the senses are exercised thereby. The same consideration is forced upon us by the action of irritants upon the conjunctiva and skin, where we can observe all gradations from purely traumatic inflammation limited in duration by the irritant to that which, though thus set up, continues long after it has ceased to act; and, finally, inflammation produced by no external cause, and therefore, as we say, idiopathic. If this is true of inflammations in general, it equally applies to the reaction of the organism to other mechanical, thermal, or chemical irritants, and, above all, to its behaviour under the influence of animal poisons. Some of these appear to be so violent and efficient that all they need is human tissues to act upon. The contagion, once brought into effectual contact with the organism, produces an invariable and inevitable sequence of effects. Such, or nearly such, may be said of vaccinia, of typhus fever, and of glanders (to take three striking examples), but even here the effect is not solely dependent on the contagion and independent of the recipient. It is a truism to say that neither croton oil, nor cantharides, nor tartar emetic ointment will produce inflammation upon the skin of a corpse, or that the hottest sun will produce no eczema on a mortified limb, but it does seem at first sight as though sufficiently hot or cold appliances and sufficiently violent poisons would produce approximately the same effects upon any living tissue. Even this, however, is not proved; we put down such and such as the lethal dose of arsenic or laudanum, but, as we know, opium eaters in Lincolnshire and arsenic eaters in Styria take much larger quantities with impunity. Morphia has no effect upon pigeons nor belladonna upon rabbits, and both arsenic and belladonna can be given to children in far larger doses than the proportion of their body weight to that of adults would dictate. Measles, small-pox, and influenza do not produce their effects in every case, even when they invade an unprotected population; some animals, though in other respects closely allied in their functions to man, are incapable of receiving certain contagia—syphilis, for example, hydrophobia, anthrax, and relapsing fever. The protective influence of most, but not of all the specific fevers against their own recurrence is a familiar fact, and belongs to the same order as the artificial protection from small-pox, as afforded by what is probably its attenuated virus (vaccinia), and the artificially produced resistance of animals to certain diseases. All of these are examples of an efficient cause of disease failing for want of a suitable object to play upon. An old man is less obnoxious to enteric fever than a child, a vaccinated child affords little hold for the virus of small-pox, a population in which measles has been endemic for centuries has impaired susceptibility to its contagion; so that we only learn how terrible this disease can be when it is allowed free play on the virgin soil of the Fiji Islands. There must be conditions, at present unknown, which protect a large number of children from scarlet fever, though exposed to infection, for it does not run through schools with the same freedom as mumps or measles or rubeola; nay, in some cases the susceptibility of the organism varies so widely that it becomes a more important element in the production of disease than the existence of contagion itself.

III. An important point in the etiology of most diseases is one which I learnt from Dr. Wilks; and, although I have not met with the observation elsewhere, it will, I feel sure, be backed by the experience of those whom I address. It is a commonplace of medical writers that acute diseases, instead of terminating by resolution, often continue in a mitigated but protracted form, and hence the malady which is at first both sharp and short (ὀξυς) becomes less severe and more protracted (χρόνικος); hence the adage: "Si dolor gravis, brevis; si longus, levis." But, though this is true in certain cases of rheumatic fever when untreated, of successive attacks of gout, of eczema, of tubal nephritis, and of malarial fever, yet the opposite order is not less important to observe—viz., that acute diseases are often developed out of chronic. The sudden seizure of a man in all the vigour of youth and health, by which the strength and ease of the morning is changed in a few hours into prostration, severe suffering, high fever, and a perverted state of every function, both of mind and body, is so striking and dramatic an event that it naturally arrested

Digitized by Google

attention. Such cases have been generally taken for description by the best medical writers, who naturally choose the most striking and picturesque aspects of disease. But probably the only maladies in which such a mode of onset is at all common are those which are contagious, and depend upon the invasion of a healthy organism by a countless swarm of foreign organisms attacking it from without. They are so numerous and their poison is so powerful that they at once overcome the utmost vigour of youth and health, just as the strongest man is immediately subdued by stifling gases or by the venom of a serpent. In most other cases of disease, however, the apparently acute outbreak is really the result of a less obvious but no less important antecedent failure of health. Even in the case of infective diseases experimental pathology teaches us that, while on the one hand an organism may be rendered refractory to the invasion of the virus, on the other hand it may be artificially prepared (as by the injection of the cultivation fluid of blue pus), so that the subsequent invasion of a very attenuated virus shall produce the most severe effects. Thus it is a matter of common experience that enteric fever often begins with certain days, or even weeks, of diarrhœa; hence arises, at least in part, the difficulty of fixing the precise date when the specific fever began. May it not be that the local conditions of the intestines render them more obnoxious to the action of the contagion when it invades? In the same way genuine diphtheria is often preceded by non-specific and subacute angina; and may not here, again, the inflamed mucous crypts and lymph follicles and desquamating epithelium prepare a favourable nidus for the reception of this specific virus? In the case of phthisis, there is reason to believe that the bacilli of tubercle seldom make a successful inroad until local pulmonary catarrh or general feebleness of health have prepared the way for their reception. But if this be to some extent true even of contagious diseases, it becomes the rule, and no longer the exception, when we study the onset of many non-specific, but acute, inflammatory disorders. Abscess of the brain is acute, severe, and rapidly fatal when once developed, but it never attacks previously healthy patients. It is always preceded by injury, by caries, or by primary suppuration. How often do we find acute lobar pneumonia, a disease in many ways allied to a specific exanthem, not occurring in its classical form as a primary attack in a previously healthy man, but as a secondary complication of cardiac disease, of enterica, of rheumatism, or of chronic Bright's disease; sometimes in patients who are bedridden, and have never been exposed to cold and wet. Acute suffocative bronchitis is very rare in the young and healthy; the vast majority of cases occur in old and decrepit persons who have long been subject to a winter cough, emphysema, and consequent dilatation of the right side of the heart. The cases of phthisis which are most inflammatory — cases of "galloping consumption" — are almost always less rapid and acute than they seem. Careful inquiry brings out in most cases the fact of failure of strength, loss of flesh, and sometimes of definite local symptoms in the chest or throat, which have long preceded the apparently sudden outbreak of the disease. Phthisis ab hæmoptoë is not infrequent as a clinical event, although pathologically hæmorrhage is probably never the origin of phthisis. But when a patient tells you that while in the enjoyment of vigorous health he burst a bloodvessel under the stress of some sudden effort, how often do we find that scarcely noticed preceding symptoms of pulmonary disease have been present, while the physical signs point to changes no longer recent? How frequently after death from what seemed to be an unusually rapid case of phthisis, does the post-mortem room reveal long antecedent and partially obsolete lesions? Even mechanical lesions, like volvulus and other terribly acute and severe forms of intestinal obstruction, are often unexpectedly shown at the necropsy (without which experience and record of such cases is all but useless) to be only the final result of slow and gradual changes which prepared for the final catastrophe. In the case of cancers, which, in spite of numerous and careful observations, are believed by many pathologists to be parasitic, or conveyed by some form of infection from without or of dyscrasia from within, is it not a truer view to regard them as in each case, not originally engrafted upon or invading the body, but springing up as a perversion of local growth, sometimes at certain periods of rapid development, as in the sarcomata of the bones and joints of children, but most particularly at the periods of involution, disuse, and degeneration? If this view be correct, we shall in many cases find that the wide, striking, and at first sight almost incredible perversion from the normal structure of the part is not so sudden or "heteroplastic" as it seems, but originates by a gradual increase from minor perversion of growth which we call inflammatory or benignant. As cases in point, I would adduce the development of cancer of the skin from warts, the relations of cancer in the breast to Paget's disease of the nipple, the supervention of mycosis fungoides upon extensive superficial dermatitis, the connexion of carcinoma linguæ with syphilitic or other leucodermic patches, of labial cancer with smoking, of cancer of the glans penis with phimosis, of carcinoma of the gall-bladder with calculus, and, lastly, the remarkable fact that the favourite seat of cancer of the alimentary canal is at the narrowest passages, where friction and irritation are most probable and frequent.

IV. We have hitherto spoken of diseases which may be considered accidental—that is, a result of circumstances,—and from which therefore, were those circumstances constantly favourable, the organism would be free. What forms of disease would still remain? First, there would in a thousand individuals of any species be a certain number which came into the world imperfectly formed. To judge from the domesticated races such malformation is far from infrequent, but places the individual at such a disadvantage that it rarely survives. Among feral tribes abnormalities and monstrosities are perhaps less frequent, and would be more certainly suppressed in the keen competition of unprotected rivalry. In the human subject congenital diseases form a comparatively small, but extremely interesting, etiological group. We must distinguish them into three very diverse kinds.

1. Deficiencies, redundancies, or abnormalities due entirely to some deviation in the development of the embryo. Familiar examples are: harelip, spina bifida, hypospadias, atresia ani, and arrested or abnormal development of the heart and great vessels. The last-mentioned group is the only one of practical importance to the physician; they were dealt with by a late Fellow of the College, Dr. Peacock, with characteristic fulness and accuracy, and if he sometimes included under this head a larger proportion of cases—as, for example, those of tricuspid stenosis—than we should now admit, the reality of such errors of development remains independently of questions as to its extent. When we have traced the origin of diseases to such congenital malformations we have reached the term of present and perhaps of future knowledge. What determines such defects, excesses or varieties, is now, and is likely to remain, a mystery. They are independent of any accidents of utero-gestation, since they are common amongst vertebrate and invertebrate animals, and also in the vegetable kingdom. Many, perhaps most, of such malformations may be regarded as extreme cases of sports or variations from the ancestral form, of which the laws are unknown and the existence unexplained by the theory of natural selection which depends on their occurrence. I would only deplore in passing the lamentable proof of how slowly superstition gives place to a rational view of natural objects which is afforded by the belief that nævi, cleft palate, and deficient limbs are due to what are called "maternal impressions," a survival pardonable and even interesting when we meet with it among ignorant villagers, but without excuse when it occurs in a learned profession. 2. The second natural class of congenital diseases are those which, though present at birth, are the result of intra-uterine disease. Lesions of the right side of the heart from fœtal endocarditis (some would say rheumatic endocarditis), deposits of lithic acid in the fœtal kidney, intra-uterine ague and variola are more or less authentic examples; but probably the most frequent, and certainly the most important, is congenital syphilis, a disease directly transmitted by infection from one or other of the parents to the offspring. 3. The third etiological group of congenital diseases are those which are derived by inheritance from the parents, for the most part developing long after birth. On this large subject of hereditary disease I will only make the following observations: First, that congenitally transmitted diseases, of which syphilis is the most important, do not come under this head. Next, that most cases of cancer, though sometimes strongly hereditary, are nevertheless in the great majority of cases not transmitted at all. Thirdly, that if, as most naturalists

Digitized by Google

agree, acquired properties are not transmitted to the offspring, it is very difficult for us to explain the undoubted hereditary transmission of gout.

As sources of fallacy in estimating the influence of heredity, we must bear in mind the probability of a son living in the same place, working in the same trade, and adopting the same habits as his father; also that very common diseases will appear to be hereditary by mere coincidence. Hence all statistical statements as to the frequency of rheumatic fever, cancer, or phthisis in the children of parents subject to these diseases ought to be checked by control figures showing its frequency in others. Lastly, we must not attempt to deal with obscure and ill-defined diseases; nothing valuable can come of statistics with respect to "rheumatism," "tonsillitis," or "epilepsy" without further definition. Yet we see jumbled together, in the attempt to establish an authentic inheritance, diseases of such different pathology as rheumatic fever, gonorrhœal synovitis and gout, and we are told that a patient's eczema is hereditary because his father suffered from urticaria, a brother from "psoriasis" (possibly syphilitic) and his maternal grandfather from gout. Or a "neurotic" inheritance is established on the strength of convulsions and paralysis having been remarkably common in the family, when we find on inquiry that the cases consist of infantile paralysis, hysteria, traumatic epilepsy, hemiplegia from embolism, and paraplegia from tubercular vertebræ. In genuine cases of hereditary disease there is transmission, not of the disease itself, as in the case of syphilis, but of some structural or functional, histological or chemical, peculiarity which renders more likely than usual the development of such diseases as gout, insanity, or hæmophili. A child born with a syphilitic rash and snuffles is not more likely than another to acquire syphilis if exposed to its contagion; it has the disease already; but a child born of decidedly gouty parentage differs from another in the ease with which the same causes which produce the disease in general will be efficient in his case. Hereditary tubercle, again, is only as a very rare exception, due to congenital transference of the virus, such that the infant enters the world with the bacilli in his tissues. In the vast majority of cases it means liability of the smaller bronchial tubes to catarrh, a vulnerability of the joints, and an excessive hospitality for the tubercular microbe or deficient capacity for dealing with him on the part of a too feeble phagocyte.

V. It has long been the custom to explain the occurrence of certain diseases by referring them to a previous existing disposition, or, to use the Greek form of the word, *diathesis*, of the patient; but it has always appeared to me that the assumption of such a cause is unscientific and prejudicial to the advance of etiology. To say that a man who has had rheumatic fever has a disposition to its recurrence is only to say that rheumatism is a disease which usually occurs more than once in the same person. We gain nothing by referring the occurrence of the rheumatism to a preceding rheumatic diathesis. If a man's father has had phthisis or gout he is no doubt predisposed to these diseases; but this, again, is only saying that phthisis and gout are often hereditary. The disposition of tendency for these or other diseases is either carried out or it is not; if it is never carried out, its existence cannot be proved, and is of no practical importance. If it is carried out, the right way to put the fact is to say that the disease occurred, and the supposed predisposition to it is only a roundabout way of repeating the assertion. If we find albuminuria and other signs of Bright's disease we may, if we please, say the patient is predisposed to apoplexy. If the blue line is on the gums, we may say that he is predisposed to paralysis of the extensors of the forearm; if he is a dram-drinker, that he has a cirrhotic diathesis. But none of these would be counted cases of diathesis in the conventional meaning of the word; and I venture altogether to deny that, apart from actual morbid events, either present or past, from hereditary taint or from such probabilities as exposure to disease from age or sex or occupation, that it is ever possible to predict the future advent of disease. Along with this lingering remnant of theoretical and metaphysical medicine we ought surely to discard from etiology such terms as "dyscrasia" and "temperament"—phrases which belong to the exploded humoral system of pathology. We know that there is no such thing as the black bile, and that phlegm is not secreted by the hypophysis cerebri; how, then, can we talk of the due temperament of the four humours or of their ill temperament, bad mixture, or dyscrasia? The division of men by their imaginary temperaments is arbitrary and without any basis, scientific or practical. It may be compared to the false sciences of phrenology and chiromancy. Lastly, if the existence of these etiological conditions is often arbitrary, what shall we say to the supposed blending of different diatheses? Just as it was found necessary to add to the four classical temperaments, and to admit "lymphatic," "nervous," and nervo-sanguineous, so it has been supposed that a hybrid disease like "rheumatic gout" can exist, and that scrofula and syphilis, herpetism and arthritism, may mix with each other, and modify the effects of a wound or the symptoms of a specific fever. All such theories appear to me to be baseless, and to prevent investigation into etiology by premature explanation. So far as such vague doctrines can be brought to the test, they fail. On the one hand, our present knowledge of the true etiology of syphilis, variola, scabies, scurvy, gout, and tubercle forbids our admitting the possibility of hybrids between an acarus and a bacillus, an amœba and a crystal; on the other hand, clinical experience shows that psoriasis, for instance, may occur in a case of syphilis, develop, and be cured quite independently of the latter, and that the same holds good of rheumatism and typhoid fever, gout and cholera, ague and pneumonia. The whole conception of complex diseases belongs to a time when each was regarded as a separate living thing, and is out of place if we look upon them as disturbed physiological conditions.[2]

VI. To go back once more to the ovum or organism in its simplest form, let us now suppose that it has inherited nothing but physiological—that is, normal—structure and tendencies; that it has met with no external disturbance, or, as we express it in medicine, is free from congenital and acquired diseases. Nevertheless, we know that it will not last for ever. One disease which was common to all its predecessors it has undoubtedly inherited as a diathesis, and this fatal heritage is a disposition to die. Its period, like theirs, is limited, and when its natural term is reached it too will cease to perform the functions of a living being, and its protoplasm will become subject to the reactions of common chemistry. Why either a cell or a more complicated vegetable or animal organism should wear out is not easy to explain; in the animal machine with which we are best acquainted its constructions and its working are so admirably contrived, so delicately adjusted, so finely compensated, that, while on the one hand we wonder that so fragile and exquisite a piece of mechanism should escape the various accidents of life or throw off the effects of injuries, we wonder scarcely less that so perfect a machine should ever wear out. If no external injury befal the body, no poison, no bacillus, no parasite approach it; if expenditure of force be restrained to the narrowest and most selfish needs of the individual, and the income of food be limited in proportion, there are yet certain expenditures which must continually go on. The diaphragm and the heart are muscles which have no prolonged holiday like those of the limbs during sleep; yet they also have their intervals of rest, no less constant than of work. And it does not appear that the musculo-nervous apparatus or the secreting organs ever cease to act by mere weariness of having toiled for fourscore years. Degeneration is not mere exhaustion of the vital powers, or using up of the first impulse which was given at conception, in the same way as a moving body gradually comes to a stop by friction, or a burning mass is quenched when the fuel is consumed. On the contrary, we can, I believe, always refer death from old age either to incidental diseases of external origin—injuries, cold, or contagia—or else to structural changes, particularly of the vascular apparatus. A continued hydraulic strain upon the great arteries is a kind of mechanical injury which leads to a chronic inflammatory process and a gradual destruction of their elasticity and power of resistance to blood-pressure.

That old people are far more liable than young to

[2] I would here venture to urge a definite abandonment of the term "scrofula." Its original application, as we all know, was to the swollen glands of the neck, and it was used at the time when the cervical lymph glands, the secreting submaxillary glands, and the "ductless gland," which we now call the thyroid, were all supposed to be much of the same nature. In modern German usage the word "struma" is not, as in England, a synonym for scrofula, but means what we call bronchocele. The traditional description of two types of scrofulous children, if it has any meaning at all, seems to apply to tuberculosis in the one case and to congenital syphilis in the other. The detection and separation of the latter condition by Mr. Hutchinson appears to me one of the principal achievements of modern English medicine.

Digitized by Google

succumb to accidental disorders, such as diarrhœa, bronchitis, pneumonia, and enteric fever, may be to some extent explained by the degenerated state of their arteries, the frequently emphysematous condition of their lungs, and the probability that one or both sides of the heart have become dilated. Deaths which are ascribed to old age may be the result of chronic diseases, which chiefly affect the latter period of life, such as cancer, granular degeneration of the kidneys, bronchitis and emphysema, apoplexy from disease of the cerebral vessels, and various forms of structural disease of the kidneys and bladder from enlargement of the prostate. Or the disease may be an accidental one to which all ages are liable, but the power of resisting it is diminished. In this last respect the two extremes of life resemble one another. The freshly lighted taper and that which is burnt down to its socket are both easily extinguished by the slightest puff of wind. Hence the mortality of typhus fever, variola, and enteric fever in persons over sixty; hence the apprehension with which we regard pneumonia in an elderly patient.[2] The most common causes of senile mortality are the same as those which are fatal among infants—diarrhœa, particularly in the summer months, and bronchitis, particularly in the winter. To these trivial disorders an old man succumbs as he does to an accidental injury, to a fracture of the thigh or the rib. When none of these external disturbances have occurred, when the long-drawn thread of life is cut at last, suddenly during tranquil sleep or in the midst of placid conversation, the cause is probably always syncope. It is the heart and bloodvessels which give out at last. We must, however, admit that old age is otherwise peculiarly vulnerable. The cartilages are calcified, the bones are brittle, and the loss of fat diminishes the elasticity of the tissues and adds to the risk of shock. The lungs are light and thin from senile emphysema, the muscular strength is greatly diminished, so that there is less power in making voluntary efforts in respiration, and the nervous system is no longer sensitive and active, so that conservative reflex movements are sluggish, and the old man can neither save himself from a fall nor appreciate the deficiency of oxygen in the blood which reaches his brain. The loss of appetite prevents due nourishment, and the bodily heat is difficult to maintain. The organs of sense are, with few exceptions, impaired, chiefly from demonstrable structural changes, but also from diminished excitability of the nervous centres. With respect to the mental powers, it is difficult to separate the action of the cerebrum from its supply of blood; in true senile dementia there is probably always arterial hæmorrhage or obstruction or wasting of the cortex. Loss of memory appears to be the only mental symptom which is constant after a certain age. We have numberless examples of high intellectual powers, of beauty and dignity of character surviving physical decay; but whatever may be the clearness of judgment, the eloquence of language and energy of will in an aged body, it would probably be found without exception that such mental exertion can only be maintained for a short time. After Sophocles had triumphantly vindicated his mental powers at ninety years of age by reading a chorus from his last tragedy, he probably did no more for that day.

SENILE TUBERCULOSIS.[1]

BY HOWARD MARSH, F.R.C.S. ENG.,
SURGEON TO, AND LECTURER ON SURGERY AT, ST. BARTHOLOMEW'S HOSPITAL.

IT will be remembered that Sir James Paget, in his Clinical Lectures, has a paper on senile scrofula. This paper reminds us of one of Bacon's "Essays." It is very short, yet in its four pages it gives such a complete epitome of the subject that it will be long before anything that is really new is added to it. The value of Sir James Paget's observations is, of course, in no degree impaired by the circumstance that they were published before the exact pathology of the disease had been discovered; but, as it has since been shown that what was formerly spoken of as scrofula or struma is really tuberculosis, I shall exchange the one term for the other, and speak of senile tuberculosis instead of senile scrofula. The subject is one of wide clinical interest and importance. The disease in its various forms is far from rare, and its diagnosis is often in its early period very difficult. I hope, therefore, I may be justified in relating and discussing some of the examples of it which I have met with. But I may first allude very briefly to the incidence of tuberculosis at other periods of life. Statistics show very clearly that surgical tuberculosis is most prevalent between the ages of three and ten. But yet it may occur at a still earlier period. I have seen, for instance, at least four cases of tubercular caries of the spine (Pott's curvature) in children under a year old, and in one the disease began when the child was only seven months. After ten, tubercular disease (for instance, of the hip or the spine) becomes steadily more rare as age advances. I have met with it in all the decades up to that between seventy and eighty, but each decade shows, I think, a progressive diminution. The bearing of age on diagnosis deserves attention, for in some instances an oversight seems to have been due to the fact that the possibility of the occurrence of tubercular disease in a patient between forty and fifty or between fifty and sixty had not been considered or even entertained. About five years ago a woman, aged forty-five, at St. Bartholomew's Hospital, who stated that she had been eight months under a surgeon—who, however, had never examined her—for "rheumatic pains and sciatica," was found to have angular curvature and a large lumbar abscess. Another patient, aged fifty-five, who had tubercular disease of her hip, was supposed for several months to be suffering with chronic rheumatism. Such cases serve to enforce the recollection that tubercular disease may be met with at any period of life As to the age at which tuberculosis should be regarded as senile I think the line may very well be drawn at fifty. This limit is an arbitrary one, but it is sound clinically; for patients who develop the disease at or after this period are usually enfeebled in general health and have tissues that are already old in the sense of being degenerate.

The following case, recently under treatment at St. Bartholomew's Hospital, may be related as a typical example of senile tuberculosis. A man aged sixty-three, but who looked seventy, applied as an out-patient for advice about his knee. This, he said, had been weak, painful, stiff, and a little swollen for two months. I regarded the case as one of senile osteo-arthritis, for this view best accorded with general probability, and was one with which the symptoms agreed. The limb was scarcely at all flexed, there was no effusion into the joint, on passive movement the leg was easily flexed to a right angle with the thigh, and there was slight grating, such as is so often found in osteo-arthritis. He was ordered a series of four small blisters, and advised to walk for the time being as little as possible. At his next visit a fortnight later, however, the synovial membrane felt more thickened and puffy, and the skin was abnormally warm and somewhat dusky and glossy. Thinking the disease was possibly tuberculous, I had his lungs examined, and he was pronounced to have phthisis. In another fortnight the joint suppurated, and a collection of pus formed on the inner side over the head of the tibia. He was now admitted into the hospital. The abscess burst the next day, and about half an ounce of caseous pus was discharged. The resulting sinus showed no tendency to heal. For two months the limb was kept on a back splint, by which the joint was maintained at complete rest; but the swelling due to synovial thickening increased, and the thigh muscles wasted. He had a troublesome cough and free expectoration. The question was discussed whether, as he had phthisis involving both lungs, amputation could be ventured upon. The risk of the operation seemed less than that of allowing him to remain confined to bed with his temperature, as it often was, at 102°. I therefore removed the limb. The wound healed by primary union in almost its whole extent, and was dressed only once. The improvement in his general health was very marked. He quickly gained flesh and strength, and his temperature became normal. This case is, I think, noteworthy, not only as one of senile tuberculosis, but as evidence on the question whether amputation should be performed when joint disease is complicated with phthisis. As to this I may say that I have on several other occasions

[2] After seventy or seventy-five sometimes a better prognosis is possible, and I have known recovery from pneumonia at eighty. This perhaps is because those who outlive threescore years and ten are picked lives, and by reason of strength survive.

[1] Paper read at the Harveian Society in February, 1892.

performed amputation for disease of either the wrist, knee, or ankle in patients with well-established phthisis, and the result has, as in this case, been in no way prejudiced by the condition of the lungs. In one, however, free hæmoptysis followed the use of ether; and it is safer, no doubt, to use chloroform in such cases.

In the Museum of St. Bartholomew's Hospital is a specimen thus described in the catalogue:—A knee-joint exhibiting well-marked pulpy degeneration of the synovial membrane. Microscopically, the thickened synovial membrane contained abundant deposits of miliary tubercle. From a lady aged sixty-seven, in whom the disease had existed for twelve months. The limb was removed by Mr. T. Smith. Two months before amputation the joint was tapped, and clear synovial fluid was removed. The patient made a very favourable recovery.

In the next four cases of senile tuberculosis the hip-joint was the part affected. A female patient aged fifty-five, who had been for some months in failing health, and who looked prematurely old, was attacked with stiffness and somewhat severe pain in the hip, attended with muscular wasting. For some months these joint symptoms were thought to be rheumatic. When I first saw her, however, the evidence that the disease was tuberculous seemed conclusive. She had phthisis, and had twice had free hæmoptysis; and the joint mischief had proceeded to suppuration, and an abscess holding about six ounces of pus was found beneath the tensor fascia femoris. Weight extension was applied and afterwards a Thomas's splint; but the disease steadily advanced, the abscess, after being opened aseptically, discharged about two ounces of pus daily, and the limb became shortened and everted. For some months the condition of the lungs appeared to be stationary, but then it became more active; there were three attacks of hæmoptysis, and purulent expectoration was free. The patient gradually wasted, and died about two years after the commencement of the disease. The hip-joint was at the time of death completely destroyed, the head of the femur had been absorbed, and the limb was two inches short and much everted.

For the following case I am indebted to Mr. Langton. A woman aged fifty-three, admitted into St. Bartholomew's Hospital in January, 1890, stated that in the previous March her left hip became painful and stiff. Gradually getting worse, she could move about only on crutches, and in the December she observed a swelling on the outer side of the joint. On examination she was found to have well-marked symptoms of hip disease—stiffness, shortening, eversion, and an abscess. The abscess was opened two days later, and subsequently counter-openings were made. She became rapidly worse; the urine (normal at first) now contained albumen. She became delirious, and died of exhaustion on April 10th. On post-mortem examination both lungs were tubercular; the right kidney was disorganised by tubercular disease; adrenals were tubercular. The hip-joint was disorganised, the head of the femur being partly destroyed, the acetabulum perforated, and a collection of pus had formed in the pelvis. The lymphatic glands running upwards along the iliac vessels and the aorta as far as the diaphragm formed a large elongated mass of tubercular glands, many of which had undergone calcareous degeneration. The head was not opened, but the symptoms observed before death seemed clearly to indicate the existence of tubercular meningitis. I may add that Mr. Bowlby informs me he recently made a post-mortem examination in which he found that a woman aged fifty-six had died of general tuberculosis and tubercular meningitis.

A man aged fifty-six had stiffness of the hip and pain extending from that joint to the knee, with marked muscular wasting. Within three months an abscess formed in Scarpa's triangle, and when this was opened a sinus, discharging pus freely, remained. The disease steadily advanced in spite of recumbency and weight extension, and the joint became disorganised. When he died from another cause fifteen months later the disease was evidently still in progress, and appeared to have become incurable.

In the College of Surgeons' Museum is a specimen thus described in the catalogue: "A hip-joint, in which, after the head and upper part of the neck of the femur had been destroyed, the shaft was drawn up, so that the remains of the neck rest in the ilium just above the acetabulum. It was taken from the body of a woman aged seventy, who ten years before her death had apparently scrofulous disease of her hip. Abscesses formed and opened in the groin, and ultimately the limb became much everted and shortened. After her death, by apoplexy, her lungs and liver were found tuberculous." This case is not only (in common with Case 2 and Case 3) a complete counterpart of hip disease in its more destructive form in the young, but as an example of senile tuberculosis is remarkable in the recovery of the patient. Such a result is, I think, very exceptional. It is much more usual to find, as in the three previous cases, that the disease advances, though it may be slowly, to a fatal termination.

I do not remember to have seen an instance of senile tuberculosis affecting the shoulder-joint, but I have met with it twice in the elbow and several times in the wrist. I may relate one case as an illustration. A man, aged sixty-seven came to the out-patients' room about six years ago with his left wrist swollen and weak, and with yielding of the ligaments, so that it was becoming distorted. The synovial membrane could be felt thickened and pulpy, and there was very marked wasting of the muscles of the forearm. To support the wrist he nursed it with his other hand. The disease, which he attributed to a wrench at his work, had been in progress four months. He complained of little pain. The hand and forearm were enclosed in carefully moulded leather splints and kept in a sling. For the next month the condition of the limb improved—swelling, heat, and redness of the skin subsided, and the joint felt, he said, much stronger. He now, without asking whether it would be safe, tried to work at his occupation as a cooper, but this produced an immediate relapse, and within three weeks an abscess formed. This was evacuated, but suppuration continued, and two sinuses remained. Suppuration was quickly followed by widespread destruction of the ligaments, so that the hand could be freely moved in all directions on the forearm, while the different carpal bones were felt, with a probe, bare and detached from each other. Amputation was therefore performed. The wound healed slowly, but without complication. On examination the whole carpus was infiltrated with curdy pus; the bones, many of them entirely denuded of cartilage, lay loose in tubercular granulation tissue, and pus had burrowed for some distance among the flexor tendons of the forearm. No microscopic examination was made, but the naked-eye appearances exactly corresponded with those of tubercular joint disease in young subjects.

One of the most rare of all the forms of senile tuberculosis is spinal caries. Sir James Paget has described a clear example of this affection in his "Studies of Old Case-books." The patient, a barrister aged about fifty-six, had pains in his back and sides, which were thought to be rheumatic. Four months later he had constant pain along the six lower ribs and at the epigastrium. Six months after the commencement of his disease, Sir James Paget found two spinous processes in the lower dorsal region prominent, and deflected to the right. With prolonged rest, and with issues kept open by the side of the spine, he slowly recovered. In four months he could sit up without pain. He regained health, and lived to be eighty-one.

I know of only three other cases: 1. In the catalogue of the College of Surgeons' Museum is a specimen (No. 3406), which is described as follows: "The five upper cervical vertebræ and the condyloid portion of the occipital bone affected at several points with ulceration (caries). The right transverse process and the lower articular surface of the same side of the atlas are entirely destroyed. The disease has also affected the corresponding condyle of the occipital bone, and the articular surface and side of the body of the axis, the right tranverse process, and the side of the body of the third, and the left occipito-atlantal articulation. No symptoms manifested themselves during life but those attributed to melancholia." As there is no history of the case, and as there was no discharge of pus during life or note that any was found after death, it may, of course, be questioned whether the disease was, as I believe, tubercular. The appearances, however, are exactly like those met with in tubercular caries, nor am I acquainted with such appearances as the result of any other form of disease. 2. I am indebted to Mr. Butlin for the following case: A healthy looking man aged sixty-seven was admitted into St. Bartholomew's Hospital in December, 1886. A month before, he had fallen off a table, and struck his neck against a chair. This injury was followed by stiffness of the neck, which gradually increased. In the following March he noticed a swelling in the neck, which gradually enlarged. In July, Mr. Butlin, finding that an abscess had formed, opened it. This relieved him, and the wound healed. In

Digitized by Google

December, he returned to the hospital, complaining of severe pain, increased on the slightest movement, and situated on the left side of the neck and head. His temperature was not raised. The head and neck were enclosed in a leather case. This gave him great relief, and enabled him to sleep in comfort. In the following January an abscess (deeply placed behind the sterno-mastoid) was opened, and healthy looking pus in considerable quantity was evacuated. In February matter was found above the right clavicle. This, which proved to be fetid, was let out. The temperature was now 103°. An attack of cellulitis of the head and neck followed, but subsided; the discharge diminished, and in October had almost entirely ceased. But in November he had further suppuration, and a temperature reaching 104°. This attack also subsided, and in December he was well enough to be discharged. The leather collar was still worn, so as to support and keep his head as far as possible at rest. His subsequent history is unknown. I frequently saw this patient, and I believe, with Mr. Butlin, that the case was certainly one of tubercular caries of the spine. 3. A man aged sixty-three was in St. Bartholomew's Hospital about six years ago, under my care, with stiffness of the neck, so that he could neither nod nor rotate his head, with considerable widening and bony thickening in the neighbourhood of the spines of the upper cervical vertebræ, and with pain radiating over the occiput and down the sides of the neck. His head had sunk forward so that his chin was nearly on his sternum, and he moved cautiously and turned over in bed with difficulty. When sitting up he supported his head with his hands as children with caries of the cervical spine often do. A leather support was supplied. No suppuration occurred while he was in the hospital, where he stayed for about five weeks. This case was in all its features so exactly similar to cases of caries of the spine in young persons that I think there could be no reasonable doubt as to its nature. In the last year I have met with a case of disease of the sacro-iliac joint in a man aged fifty-four, in connexion with which a large abscess formed and burst, leaving a freely discharging sinus: and I know of another case in which the patient, a man aged fifty-five, died of exhaustion following disease of this joint attended with profuse suppuration.

In senile tuberculosis of the small bones of the hand and foot, and of the testis, the appearances are very similar to those which characterise tubercular disease of these parts in young subjects. There are the development of swelling arising without obvious cause or after injury, and its steady though slow and often painless increase, the infiltration and dusky tint of the skin, the formation of matter escaping through sinuses which usually show little or no tendency to heal, and, later, the thinning, undermining, and retraction of the skin, so that more or less extensive ulceration results. In the course of last year I saw in the out-patients' room two men, one aged sixty-six and the other seventy-two, with senile tuberculosis of the testis. In the first only one testis was affected, in the other both. In both the epididymis was enlarged, hard, and rugged, the skin was dusky and adherent, and suppuration had taken place. In the one the disease quieted down by rest and careful dressing, though when the patient was last seen a small sinus was still discharging and the epididymis was still large and hard. In the other the disease was advancing when the patient was last seen, but I am not aware how the case ended.

I do not know whether I am correct, but my impression is that senile tuberculosis of the lymphatic glands is rare. I have seen it going on to suppuration in the neck in two cases, but these two are all I can remember. Mr. Kiallmark, however, informs me that ten years ago a lady aged sixty-five had a mass of enlarged glands in the axilla, which had suppurated and led to the formation of several sinuses. The disease had been regarded by two surgeons as carcinoma. Mr. Kiallmark, however, considered that the affection was tubercular, and in this view he was confirmed by Sir James Paget. Under treatment the patient made a good recovery, and is still in good health. Disease of the lymphatics calls for no detailed description, for it is, though perhaps more chronic, generally identical in its characters and its course with the like affection in young subjects. That the lymphatics may become widely involved as the result of joint disease, just as they may in hip disease in earlier periods of life, is well shown in one of the cases related above.

The most material part of the subject of senile tuberculosis from a clinical point of view is the diagnosis of the affection in the different forms in which it may present itself. This may, as I have said, be attended with great difficulty—indeed, in the early stage of the affection it may be almost impossible. In the spine and the joints it will be a question between this disease and some form of osteo-arthritis. At first the symptoms may afford no reliable clue, and the surgeon, while trusting to general probability, and therefore anticipating that the case will prove to be osteo-arthritis, will yet do well to remember that, after all, it may be senile tuberculosis, and be ready to take note of any further indications that may present themselves. In the case of the spine, the development of angular curvature would of course point almost conclusively to tuberculosis. This symptom was well marked in the case recorded by Sir James Paget. It would be available, however, only in the dorsal and lumbar regions. In the cervical region senile equally with earlier tuberculosis produces deformity, but the deformity is not characteristic. It may consist of alteration of the axis of the column in a direction either forwards or laterally, or obliquely between these two; but the same deflection may occur in old people from osteo-arthritis, and also from muscular and ligamentous degeneration. I occasionally see a man of seventy-four with paralysis agitans, whose chin rests on his sternum, and whose cervical spine has such an abrupt bend forwards that it presents all the appearances of an angular curvature involving two or three vertebræ. Even angular curvature in the dorsal or lumbar region must not be regarded as an absolutely conclusive proof of the existence of tuberculosis, for I know of a case in which a well-marked angular curvature in the middle of the dorsal region followed cancerous deposit in the vertebræ, secondary to scirrhus of the mammary gland. Pain is no trustworthy guide. It is sometimes very severe—it was so from the first in one of the hip cases related above, and also in the knee case first related,—but more commonly it is only slight; while sometimes, as in tubercular disease in the young, it is entirely absent. Swelling varies in its amount. In some cases of senile tuberculosis of the knee, elbow, and wrist it is slight; but in others it is much more marked than it usually is in the early period of osteo-arthritis, and is due to pulpy thickening of the synovial membrane exactly resembling that which is so commonly present in younger subjects. It has seemed to me that this is a symptom upon which some stress may be laid. Stiffness, when tested by manipulation, is sometimes in senile tuberculosis much more marked than in the early stage of osteo-arthritis, but in the knee case movement was but little restricted. Two important symptoms of senile tuberculosis, absent in osteo-arthritis, are dusky congestion of the skin and increase of the temperature of the part. The one event, however, which may be regarded as very nearly conclusive is the occurrence of suppuration. Suppuration, as a rule, occurs in senile tuberculosis, and generally it occurs somewhat early; while in osteo-arthritis it is of course exceedingly rare. I do not remember to have seen an instance of it. In two of the cases of senile tuberculosis of the hip-joint, and in that of the knee which I have related, it was mainly on the presence of suppuration that the diagnosis was based.

In cases in which the lymphatic glands are the structures affected, the diagnosis will usually lie between senile tuberculosis and malignant disease. Here, again, the occurrence of suppuration would point very strongly to the former condition, but it would not be conclusive, for, rare as it certainly is, suppuration may be met with as a complication of malignant disease. This is well illustrated in a case which I recorded in the St. Bartholomew's Hospital Reports, vol. xxiii. A man aged seventy-three had enlargement of several of the cervical glands. They were about the size of walnuts, were covered with dusky and inflamed skin, and were suppurating freely. At first sight they had every appearance of being the seat of senile tuberculosis, except that they were extremely hard. They proved, however, to be undoubtedly malignant. In some cases family history, either of tuberculosis on the one hand, or of osteo-arthritis on the other, might be so strong that some weight might be attached to it; but family history is usually no safe guide. The presence of phthisis in the lungs, however, would, as it did in one of my cases of hip disease, and in the knee case, point strongly to tuberculosis.

I have little to say in regard to prognosis and treatment. Prognosis is usually unfavourable. The disease shows a strong tendency to advance and extend. In three out of

Digitized by Google

the four cases of hip disease it steadily progressed, and in two proved fatal. Amputation has been ultimately necessary in the majority of cases of the knee and wrist. It will be noticed, however, that the woman whose hip I brought from the College recovered from very extensive disease, attended with the formation of sinuses. Sir James Paget's case of spinal disease also recovered. As to treatment, rest must, as in young subjects, be provided. The general health must be, as far as possible, maintained. Should suppuration occur, matter must be evacuated at once, the greatest possible care being taken to prevent sepsis. Should the disease continue to advance, amputation may become unavoidable. This operation, if resorted to early enough, will, so far as I have seen, be followed by a favourable healing of the wound.

Bruton-street, W.

CHANCRE OF THE LIP.

By STEPHEN PAGET, F.R.C.S.,

SENIOR ASSISTANT SURGEON TO THE METROPOLITAN HOSPITAL AND TO THE WEST LONDON HOSPITAL.

TWO cases of chancre of the lip which came under my care led me to make this abstract from the literature of the subject. Chancre of the lip may occur at any time of life, from infancy to old age; it is found in every condition of life, and under every possible variety of circumstances. The accidents which cause it are so many and so curious that no story is too improbable to be true; nothing is more strange than the facts in some of these cases, where the poison has been "ricochetting" among the members of a family or the workmen at a factory. It has fifty ways of gaining an entrance; the list is too long to be given here of all the instruments, implements, and things in daily use that have served to carry it. Probably the chancres thus caused are almost equal in number to those that are due to immediate infection by kissing, by suckling with a syphilitic breast, by such methods as these, and by unnatural practices.

Chancre of the lip is far the most common of all the extra-genital or erratic chancres. Thus, Mason found that of 37 cases of erratic chancre, 11 were cases of chancre of the lip; Laverque found 10 out of 27, Lavallée 16 out of 45, Bulkley 30 out of 65, Ricord 12 out of 29, Neumann 54 out of 84, and Pospelow 49 out of 198; Nivet, out of 581, found 412 on the face; and Tschistiakoff has collected 897 cases of erratic chancre, of which 391 were on the lip. As regards the proportion of chancres of the lip to chancres of the generative organs, it varies much, according to the class of cases to be considered. Thus Petersen of St. Petersburg had in seven years 1208 cases of primary syphilis in men. In only 23 was the chancre erratic, and in 11 of these it was on the lip. Sigmund of Vienna in seven years saw 73 cases of chancre of the lip, of which 32 were hospital patients and 41 private. Mauriac collected 1773 cases of primary syphilis in men. In 76 the chancre was erratic, and in 36 of these it was on the lip. Wirpscha, in ten years' work in a Russian hospital, saw 5147 cases of primary syphilis, in 249 of which the sore was erratic. Professor Ge of Kazan puts the proportion of extra-genital to genital chancres at 3·8 per cent. in man and 18·9 per cent. in woman. Bogolubow of Kronstadt saw 753 cases of primary syphilis. In only 4 of these was the chancre extra-genital, 2 of them being on the lip. Fournier, in twenty-seven years of private practice alone, saw 887 cases of primary syphilis in women. Of these, in 42 the chancre was extra-genital. Ricord, in 471 cases, found 29 extra-genital. But the most appalling statements are made as to some parts of Russia. Petersen is reported to have said, in 1888, that in the villages in the interior of Russia extra-genital infection occurs in 75 per cent. of the cases of syphilis, and is especially common among children. Pospelow, writing in 1889, says that in Kursk extra-genital infection occurs in 85 per cent. of the cases of syphilis, and in Wladimir in 91·3 per cent. (this includes 7·7 per cent. of hereditary cases), and that infection took place by the mouth in 63·9 per cent. of these. Ssabinin is reported to have said, at a medical congress in Russia in 1887, that of 865 cases of syphilis, 201 came of sexual intercourse, 219 were hereditary, and 445 came of herding together and using the things of daily life in common—e.g., all eating from one bowl, and passing one wooden ladle from mouth to mouth.

I know of no other figures so bad as these; but isolated instances in other countries have been published, where the poison has gone to one after another in a family, and bad outbreaks used to occur among glass-blowers, who pass their hot rough iron blowpipes from mouth to mouth. Dechaux gives an account of ten men thus infected by one man, who carried his disease (syphilitic caries of the nasal bones) from one glass-works to another. Attempts were made to get the men to use each a mouthpiece of his own, but they would not give the time to do this. Guinard, a factory surgeon at Rive-de-Gier, stamped out an outbreak by making regular monthly examinations of the men's mouths. Sigmund, writing in 1863, observed that there had lately been a run of cases of chancre of the lip at Vienna, and in 1868 he said again that these cases are on the increase. In 1850 there was a kind of panic in Vienna, and all secondary sores of the lips were popularly ascribed to direct infection, supposed to come from cigars. There is no evidence that I can find that either cigars or cigarettes have ever been infected at the tobacco factories; indeed, from the cleanliness demanded of the workpeople, and from the nature of the process, such a thing is not possible. Of course the use of another man's pipe or cigar end has in many cases been the cause of syphilis.

As regards the condition of the lip at the moment of inoculation, there is no reason to doubt that in most cases there is nothing amiss with it. But sometimes the poison takes advantage of an old crack or fissure, such as is very common, especially in winter, on either lip, especially the lower. Mr. Cooper gives a case where a crack of ten years' duration became the seat of a chancre. Similar cases are recorded by other English surgeons; and Pospelow says that out of forty-nine chancres of the lip a large number had begun in a simple fissure. Or there may be a scratch or a cut on the lip at the time of infection. In one case a bite was the cause; in another a man scratched his lip a few hours before it was exposed to infection; in another a child fell and cut her lip, and was infected by the kiss given to stop her crying. Vidal saw a chancre imposed on a chronic eczema of the lip in a young girl. Girode saw a chancre of the lip in a match-maker who was suffering from phosphorus necrosis with ulceration of the gums.

Coincident chancres of the lip and of the generative organs, the finger, or the nipple have been recorded. Roussel saw an infant with chancres of the lip and perineum. Sigmund saw seven cases of coincident chancres of the lip and tongue. In a few cases there have been two chancres on the lip, or one on each lip.

It may be well to take first the cases of chancre of the lip in children, for they are in some ways apart from the rest; and if such a case be not read aright, wrong judgments and false accusations will come of it. Thus, in one case, an infant was said to have been syphilised by vaccination, but it had a chancre at the corner of its mouth, and both of its nurses were found to be syphilitic. In another similar case the infection came not from the nurse's nipple, but from an accidental chancre on her finger. Often the chancre is overlooked, and then the disease is called hereditary. Infants are infected not only by a kiss, or from a syphilitic nipple, but also by the habit of nurses of first putting into their own mouths the toys that infants suck. Bryant had two cases of chancre of the lower lip in boys of seven; Laverque saw it in a child of three and a boy of twelve. Roussel gives seven good cases in infants and young children. These are but a few instances of what is probably not a rare complaint. Pellizzari says, "Perhaps not one case in ten comes to the notice of a doctor." In infants, he says, a chancre of the lip is a superficial lesion, which soon disappears; it is to the peculiar enlargement of the lymphatic glands that we must look, to make sure of our diagnosis. It seems certain that in infants a chancre of the lip may lack that induration which is its mark in later life. Thus Lavallée gives the case of a mother who got a chancre of the nipple by nursing a strange child, and in this way infected her own infant; but no sure signs of a chancre were ever seen on her child's mouth. Rollet, in 1859, writes: "I have tried in vain to find a case of hard chancre of the mouth in infancy. It is infinitely hard to find it on the lips or tongues of infants at the breast, though mucous patches and plaques are very common. Moreover, it is only in a few cases that you find the lymphatic glands

Digitized by Google

using the things of daily life in common—eating from one bowl, and passing one wooden ladle from mouth to mouth.

I know of no other figures so bad as this; isolated instances in other countries have been quite where the poison has gone to one after another in a long and bad outbreaks used to occur among glass-blowers pass their hot rough iron blowpipes from mouth to mouth. Dechaux gives an account of ten men thus infected by man, who carried his disease (syphilitic caries of the bones) from one glass-works to another. Attempts made to get the men to use each a mouthpiece of his but they would not give the time to do this. Grisolle factory surgeon at Rive-de-Gier, stamped out the by making regular monthly examinations of the mouths. Sigmund, writing in 1863, observed that had lately been a run of cases of chancre of the Vienna, and in 1868 he said again that there was the increase. In 1850 there was a kind of panic in and all secondary sores of the lips were popularly to direct infection, supposed to come from cigars. no evidence that I can find that either cigars or have ever been infected at the tobacco factories: the cleanliness demanded of the workpeople, and nature of the process, such a thing is not possible. course the use of another man's pipe or cigar many cases been the cause of syphilis.

As regards the condition of the lip at the inoculation, there is no reason to doubt that there is nothing amiss with it. But sometimes takes advantage of an old crack or fissure, even common, especially in winter, on either lip, lower. Mr. Cooper gives a case where a crack of duration became the seat of a chancre. Similar recorded by other English surgeons; and Puzos that out of forty-nine chancres of the lip I have had begun in a simple fissure. Or there may or a cut on the lip at the time of infection. bite was the cause: in another a man scratched few hours before it was exposed to infection: child fell and cut her lip, and was infected by to stop her crying. Vidal saw a chancre in chronic eczema of the lip in a young girl. chancre of the lip in a match-maker who was phosphorus necrosis with ulceration of the gums.

Coincident chancres of the lip and of the organs, the finger, or the nipple have been Rousset saw an infant with chancres of the perineum. Sigmund saw seven cases of coincident of the lip and tongue. In a few cases there chancres on the lip, or one on each lip.

It may be well to take first the cases of the lip in children, for they are in some ways the rest; and if such a case be not read aright, ments and false accusations will come of it. case, an infant was said to have been syphilised tion, but it had a chancre at the corner of its both of its nurses were found to be syphilitic. similar case the infection came not from the but from an accidental chancre on her finger. chancre is overlooked, and then the disease is tary. Infants are infected not only by a kiss, syphilitic nipple, but also by the habit of nursed into their own mouths the toys that infants suck. had two cases of chancre of the lower lip in boys of Laverque saw it in a child of three and a boy of Rousset gives seven good cases in infants and young These are but a few instances of what is probably complaint. Pellizzari says, "Perhaps not one case comes to the notice of a doctor." In infants a chancre of the lip is a superficial lesion, soon disappears; it is to the peculiar enlargement the lymphatic glands that we must look, to make of our diagnosis. It seems certain that in infants of the lip may lack that induration which is so in later life. Thus Lavallée gives the case of a who got a chancre of the nipple by nursing a stranger and in this way infected her own infant; but no of a chancre were ever seen on her child's mouth. in 1859, writes: "I have tried in vain to find a chancre of the mouth in infancy. It is infinitely find it on the lips or tongues of infants at the breast. mucous patches and plaques are very common. In a few cases that you find the hypertrophied

enlarged." He is so sure of this statement that he invents a theory to explain it. But induration of the sore and enlargement of the glands are noted in more than one of Roussel's cases, aged one and a half to three years; and enlargement of the glands occurred even in an infant at the breast. In Baum's case, a child four years and a half old, the sore was as hard as cartilage, and there was great enlargement of the submaxillary and cervical glands.

As regards the later stages of syphilis thus acquired in infancy, it is said by Roussel that, as a rule, it is not severe; whereas in nurses who are infected by suckling syphilitic infants, the later stages of the disease are usually of marked severity. Pellizzari, who gives a list of sixty-nine nurses thus diseased—"a long list of martyrs,"—is of the same opinion. One of them, in spite of careful treatment, fought for six years against repeated outbursts of the disease, and died exhausted, yet free from visceral disease. Plummert gives two cases of nurses who were attacked by tertiary syphilis within a few months of infection. It may be that the severity of the disease in nurses thus subjected to it is due to their health and strength being depressed at the time of infection.

We come now to chancre of the lip in adults. It is most common in the years between twenty and forty. As to its frequency in England, we have the statement of Mr. Cripps, at the Medical Society in 1887, that about 40 cases had attended at St. Bartholomew's Hospital during the past year. In Paris, at the Hôpital St. Louis, in three recent years there were 27, 49, and 45 cases respectively. The question whether it is more common in men than in women is answered differently by different writers. Most of them say the latter. Neumann found it in 21 men and 33 women; Pospelow found it in 40 men and 64 women; Sigmund in 17 men and 56 women; and Wirpscha in 50 men, 99 women, and 100 children. Bumstead and Taylor, on the other hand, put it at 471 men to 130 women. The question whether it is more common on the upper lip than on the lower is of no practical interest, nor can it be answered. Neumann found 18 on the upper lip, 28 on the lower, and 8 at one corner of the mouth; Pospelow, Ricord, and Puché found it more often on the upper lip; Sigmund saw 39 on the upper lip, 16 on the lower, 12 involving both lips, and 4 at one corner of the mouth.

Chancre of the lip in adults does not come to the notice of the surgeon till it is well advanced. Like chancres elsewhere, it may manifest itself, says Sigmund, either by increased growth, as a lump, or by destruction of the tissues, as an ulcer. In the first case it begins as a mere scaly patch of epithelium, with slight swelling of the corium; its surface is more or less fissured, and the fissures may bleed. Thus a scab is formed of epithelial débris mixed with serum and blood, whitish, yellow, or dark, thin or thick, equal in size and shape to the sore beneath it, and in most cases firmly adhering to it. The sore is indurated, and this induration may be superficial, involving only the skin and subcutaneous tissue, or it may go deeper. After a time the swelling increases, the scab becomes loose, and the corium is exposed, with its surface rough with flakes of epithelium and dried discharge. New epithelium is slowly formed round the sore; but it is smooth, thin, and weak, falling off from time to time so long as any swelling and induration remain in the sore. Only after many failures does it at last succeed in healing the sore, leaving the lip sound and smooth without a scar. The second kind of sore, where there is loss of substance, is less common; it owes its ulceration, for the most part, to causes other than itself. At or near the time of inoculation there was a scratch, crack, or ulcer on the lip; or the sore was made worse by smoking, or by the use of caustics, or by neglect and want of cleanliness, or by the rubbing of a tooth. Bad air, bad food, and a bad state of health may have the same result, bringing about a loss of substance and a purulent discharge; but this discharge is not profuse or obstinate, save in those who are utterly unhealthy. Or the sore may become the seat of phagedænic ulceration. The progress of the sore is slow, especially in elderly people. Ricord thinks that the natural tension of the lip interferes with the healing process. The induration usually takes some months to disappear. He believes that he has seen traces of it after nine years in one case and after thirty years in another. There is a scar, "or, rather, a characteristic stain, a special mark of the disease; a round, brownish, dull, bronzed patch, very slow to change." This fades at last, leaving a faint white mark, or no visible trace of any kind.

Pospelow says of his cases that the chancres varied in size from a split pea to that of a five-mark piece. In shape they were most of them round or oval; some were linear, at right angles to the long axis of the lip; a few were set obliquely on the lip, or were irregular in outline. The linear chancres probably started in simple fissures of the lip. Some of the chancres were raised, some flat, some excavated. There was in every case well-marked induration; in one only is it said that this was not found. In a few cases it was only superficial, like a thin disc of parchment. The sores were usually painful on pressure, or in such movements as were caused by the taking of food.

Ricord (1858) says: "The period of incubation is very variable. If the lip is predisposed for inoculation by a wound, crack, or abrasion, however slight, the chancre appears all the sooner; and in one such case it showed itself in forty-eight hours. Its first appearance may be as a little wound, linear or circular; or it may begin as a pustule. A chancre inside the mouth always tends to ulceration; chancre of the lip seldom goes on to deep ulceration. If it occurs at the corner of the mouth it is usually divided transversely by a deep ulcerated crack." As regards the earliest aspect of a chancre of the lip, from the patient's account it seems that what is first noticed is a papule, pustule, or fissure. In a case published by Mr. Sheild a chancre near the angle of the mouth in a woman of thirty-two began as a "small pimple like a gnat-bite." In a case of Ricord's where the lip was scratched just before inoculation, it began as a white vesicle with a red halo. If it starts in an old fissure, nothing more is observed at first than a slight glazing and hardening of the edges of the crack, which may now be a little painful.

If a chancre, or part of a chancre, be on the inner aspect of the lip, warm, moist, and sheltered, it remains smooth or eroded, and no scab forms on it; it is less raised, or almost flat, or hollow. Pospelow notes that in cases where the sore lay in this way, more or less within the cavity of the mouth, it was just like a mucous tubercle. In Mr. Cooper's case, where a lower lip, cracked for many years, got poisoned from a dirty glass, the crack became glazed and hard, especially along its lower half; and a week later, on the inner aspect of the lip, there was a typical mucous patch, which joined the original sore just where the lips touch. "The contrast between the almost dry and glazed appearance of the lesion on the part of the lip exposed to the air, and the opaline moist appearance of that within the mouth, was very striking." So, too, if such chancres ulcerate, the ulceration is likely to be more extensive towards the inner aspect of the lip.

The lymphatic glands in chancre of the lip are of supreme importance for diagnosis; they are a constant and conspicuous sign of the disease, a token that is never wanting and never doubtful. Their enlargement takes place within three weeks of the first appearance of the sore, and in most cases within a fortnight. After the submaxillary, the cervical, and even the axillary glands may suffer. In chancre of the lower lip the glands beneath the chin are often enlarged. The deep glands escape, or are less enlarged in chancre of the lip than they are in chancre of the tonsil. The enlarged glands may attain a great size, and may form a lump almost as large as one's fist. One or more lymphatics have been felt in a few cases, as thick hard cords passing from the sore towards the glands; and in such cases the enlargement of the glands themselves may be but slight. In feeble persons, or if the sore is inflamed, the glands may be painful, may become acutely inflamed, and may even go on to suppuration. Besnier had a case where erysipelas of the face started in a chancre of the lip. When it subsided, the œdema and ulceration of the lip were found cured, and the sore itself was much smaller; but the glands suppurated. Save for such accidents as these, the glands remain painless and indolent. They have the feel of syphilitic and not of cancerous glands; though they may be "as hard as wood," yet they are not "as hard as stone"; they still feel like glands, and not like the ill-defined adherent infiltrating growth of cancer; the skin is free above them; they are not matted together and wedged in among the deeper structures; they remain distinct and loose long after they have become so large that if they were cancerous they would be firmly fixed to everything round them. They are best felt by hooking one's finger up behind them, so that they lie in front of it; then they feel like

Digitized by Google

marbles in a bag, or "like nuts in a monkey's cheek." Sometimes one or two glands may far exceed the rest in size. If the general glandular enlargement of constitutional syphilis be well marked, the submaxillary glands will yet excel both in size and in hardness. They are, indeed, one of the surest and safest guides in diagnosis; and when once their hardness and enlargement are well established the case must be treated without delay.

As regards the further course of the sore itself, and the size to which it may attain if it be neglected, Mr. Hutchinson, in his "Archives of Surgery" for October last, has figured the largest one of all that he has seen; it occurred in a young lady, and invaded the whole upper lip. Other cases as bad as this have been recorded by other writers. As to the amount of inflammation in and around the sore, and throughout the rest of the lip, it varies according as the sore has been kept clean and quiet, or has been scratched or irritated. In a case of my own, in a young girl, who had been treated for three months with various lotions, the sore was large, raised, and inflamed, with a thick, dark scab, and the whole lip was red, stiff, and greatly swollen. This general swelling of the lip may reach an enormous size, and give much pain; it may not wholly subside for a couple of years. Such are the cases of "œdema indurativum," "œdème dur scléreux," "sclerotic œdema;" of late years a special organism (streptococcus) has been found in great quantities in the infiltrated tissues.

As regards the prognosis in chancre of the lip, the disease will probably run its usual course, neither more nor less. Neumann, speaking of eighty-four extra-genital chancres, fifty-four of which were on the lips, says: "The disease and its results were in no way modified by the unusual method of propagation." Sigmund says of his seventy-three cases: "There is nothing special to say as to the course and close of the disease in these cases. I observed forty-four of them for a long time without seeing them deviate from the ordinary way of syphilis. The old idea that the attack is milder if the sore is extra-genital, is certainly false as regards either a chancre on the finger or a chancre on the lip." In England the "old idea" is not that the attack will be milder, but that it will be more severe. Mr. Hutchinson, though he shows that the site of inoculation cannot affect the action of the poison, points out that neglect of treatment in chancre of the lip will result in an aggravation of the rash; and perhaps this may explain the apparent gravity of these cases. Again, Baum has suggested that some erratic chancres may, from the accident of their position, resist absorption, and thus a copious rash may coincide with a still large and indurated chancre, making things seem worse than they really are. Again, the position of a large chancre of the lip, half inside the mouth, must favour the absorption of syphilitic discharge into the stomach; and it is said that the most severe and obstinate forms of secondary and tertiary syphilis are found in those patients who have had, or still have, extensive ulceration of the fauces. And if Fournier's rule be true, that extensive ulceration of a chancre tends to be followed by a worse rash, this also will apply to ulcerated chancres of the lip. Thus there are reasons—some real, some only apparent—for the belief that a chancre of the lip will be followed by syphilis of at least an average severity, and probably rather above than below the average.

There is another "old idea" which may here be mentioned. It is the non-occurrence of erratic soft sores on the face—a great theme for discussion among the older pathologists, when as yet the distinction between infecting and non-infecting sores was not universally received. Ricord says: "I have now shown you a great number of cases of erratic soft sore in many different parts of the body; everywhere, indeed, save only on the head and face. My colleagues have not been more fortunate than myself. If we search the statistics, French and foreign, we find only two cases of soft sore on the lip, and both of these are doubtful. I believe that it ought to exist; I long to find it; but there is not one clear case of soft sore of the face." Fournier, in 1858, collected 150 cases of primary venereal sores on the head and face, but they were all hard chancres save five, and these five were all doubtful. Of course the soft sore can be produced anywhere by deliberate inoculation. Puché and Rollet thus produced it on the head or face in twenty cases; Bassereau, Huebbenet, and Robert also produced it on the lips and elsewhere on the face in many cases. But the records of true accidental inoculation of it on the face are rare and uncertain. One case that Fournier reports may be a real instance of it. Puché also reports a case of a sore on the lower lip, which had all the characters of a soft sore, and was reproduced elsewhere by inoculations; and Bryant published a case of "soft chancre" of the corner of the mouth, with inflamed glands, in a girl of seventeen; but these three cases are all that I can find. As regards the frequency of erratic soft sores in general, Fournier, out of 445 cases of soft sores, had only three or four where the sore was erratic; and Debauge, in 206 similar cases, had not one case of erratic soft sore. But the whole question must remain uncertain, in view of the character of the soft sore, and of its misleading likeness to tuberculous ulceration.

The diagnosis and treatment of chancre of the lip remain to be considered. Besides the use of mercury, the sore must be firmly covered, and the patient must be told in strong language that he is a constant source of danger to all about him. Sigmund recommends that the sore be cleansed with sublimate lotion and covered with mercurial plaster. As to diagnosis, one of two mistakes may be made. Either the chancre is taken for a simple swelling, or boil, or inflamed spot in the lip, and is neglected; or it is taken for cancer, and is excised. Records of the first mistake are too frequent to be quoted here. The second mistake is well illustrated by two cases published by Mr. Quain in 1859: "After a good deal of examination and consultation upon each of these cases, the tumours were removed." Mason gives three cases, all of which were first diagnosed as cases of cancer. Moreover, he gives the case of a man of twenty-six, who was three times within two months subjected to operation for a chancre of the lip.

Chancre of the lip is commonest in the young and middle-aged; as common on the upper as on the lower lip; and as common in women as in men. Chancre is rapid; its scab is often dark and rupial; the lip is often red, swollen, and stiff; it is seldom destructive, painful, or fetid. The glands in chancre swell in a few days; they rapidly attain a great size, yet are still loose, movable, distinct, true amygdaloid glands. Mercury will put an end to doubt. The microscope has been used with success; in two cases a suspicious sore was thus shown to be only the infiltrated granulation tissue of a chancre. But the surest guide of all in a doubtful case is the state of the glands.

Wimpole-street, W.

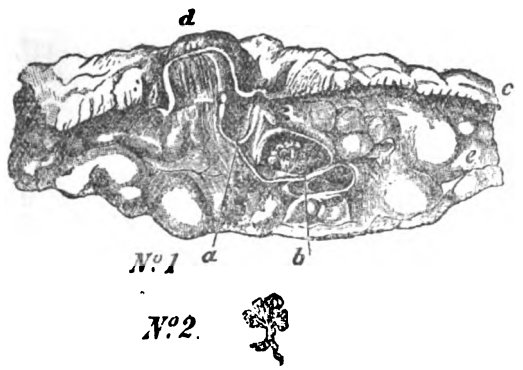
REMARKS ON SO-CALLED VILLOUS DUCT CANCERS OF THE FEMALE BREAST.[1]

BY W. ROGER WILLIAMS, F.R.C.S ENG.,
LATE SURGEON TO THE WESTERN GENERAL DISPENSARY AND SURGICAL REGISTRAR TO THE MIDDLESEX HOSPITAL.

No chapter in the history of mammary neoplasms is more obscure than that which refers to the so-called villous duct cancers. This is strikingly exemplified by the many designations applied to them by different observers. It may be worth while to reproduce some of these, since they doubtlessly indicate, however imperfectly, varied aspects of the morbid process. They have been described by Brodie as "sero-cystic tumours," by Billroth as "tubular cyst-adenomas," by Gross as "true adenomas," by Labbé as "epithelioma intra-canaliculaire," by Rindfleisch as "glandular cancroids," by Cornil and Ranvier as "carcinôme villeux"; while others have given them such names as "duct papilloma," "papillary endo-canalicular fibroma," "cystic adenoma," "blood cyst," "épithéliôme cylindrique," "épithéliôme kystique," "épithéliôme polykystique," "villous duct epithelioma," "hæmorrhagic carcinoma," "duct cancer," "tubular carcinoma," &c. What confusion all this implies! Yet there is no lack of facts; the problem rather is to set these in order and to interpret them aright. To this end I think the first and most important step is the recognition of the fact that under this term "villous cancer," as commonly employed, at least two perfectly distinct kinds of neoplasm are included—viz., the non-malignant villous papilloma and the malignant tubular cancer.

I will now proceed to sketch briefly the salient features of

[1] A paper read before the Preston Medico-Ethical Society on March 9th, 1892.



Digitized by Google

each of these varieties, basing my remarks on the study of thirty-six cases, some of which have come under my own observation.

I. VILLOUS PAPILLOMA.

Villous papillomata of the breast may be either single or multiple. They may arise from any part of the mammary duct system, but hardly ever from the acini. The galactophorous ducts are their favourite seats, especially the lacteal sinuses. (See Fig. 1.) In its simplest form the disease presents as a soft, granulated or shaggy, pea-sized, solitary outgrowth of reddish or purplish colour, connected by a slender stalk with the wall of the duct whence it originates, as in cases by Barker, Bryant, Bowlby, Pollard, and others. When such a growth is floated in water, its branching, arborescent structure at once becomes apparent. Its delicate villosities, which are often of extreme complexity, are of course easily lacerated; and as they contain large capillary blood-vessels, ecchymoses and hæmorrhages frequently result. Their prevalent dark colouration is ascribable to this, and it has often caused them to be mistaken for blood-clots, and even for melanosis. On careful dissection it is easily determined that the cavity within which the papilloma is contained is the dilated duct itself, and the fluid contents are derived from its lining membrane. These may be either serous, mucoid, or pultaceous, and they are often blood-stained; they may contain epithelial cells in granulo-fatty degeneration, corpuscles of Glüge, leuco-

Vertical section through the raspberry-like papilloma of No. 1. It is seen to be made up of four main lobes, each of them divisible into smaller leaflets. (Barker.)

cytes, granular débris, cholesterine scales, blood-corpuscles, &c., as well as dissolved albumen. These neoplasms present as circumscribed tumours of ovoid or conoid shape, with their long axes parallel to the main ducts. They are usually centrally situated beneath the nipple or areola. Though connected with the breast itself, they seldom adhere to other adjacent structures. They cause no retraction of the nipple or of the overlying skin; but these parts are sometimes dragged upon. The tumours feel firm, elastic or fluctuating, but they seldom attain large size, the majority being like filberts or walnuts. Their peripheral villosities occasionally protrude through the dilated galactophorous ducts at the summit of the nipple, where they form red granular excrescences.

More common than these solitary papillomata are the multiple ones (Fig. 2), of which cases have been recorded by Billroth, Pollard, Labbé, Robinson, and others. These may be confined to the ducts of several adjacent lobules, or to those of an entire lobe, or they may be scattered irregularly throughout the ducts of the whole gland. Under these circumstances firm, irregular, nodular tumours are produced, which often attain considerable size. On section numerous small cystic cavities are noticeable, within which the villous growths are contained; when the latter grow freely they sometimes cause absorption of the intervening cyst walls, the result being a softish mass of coalesced villous growths, which on section presents a spongoid appearance, its meshes containing pultaceous or mucoid fluid, derived from the cells lining the closely packed villosities. In these cases there is often no distinct capsule, and the bulging intra-canalicular growths may even seem to infiltrate the surrounding fibro-fatty structures.

Microscopical examination of mammary papillomata shows them to be composed of a slender framework of fibrous connective tissue, lined by one or more layers of columnar or subcolumnar epithelium. (Figs. 3 and 4.) In this fibrous framework very few, if any, cellular elements can be detected. It serves the purpose of supporting the capillary bloodvessels. In some instances this epithelial investment is exceedingly thick; upwards of twenty layers of cells have been counted. Under these circumstances the more superficial cells lose their columnar form and undergo granulo-fatty changes. Cells similar to those which cover

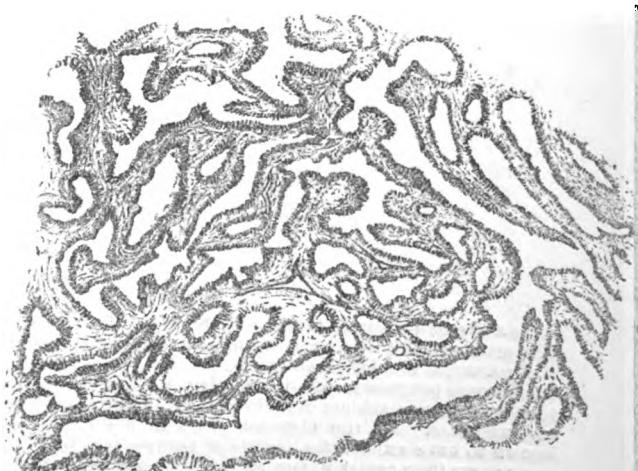

FIG. 2.

Multiple villous papilloma. (Gross.)

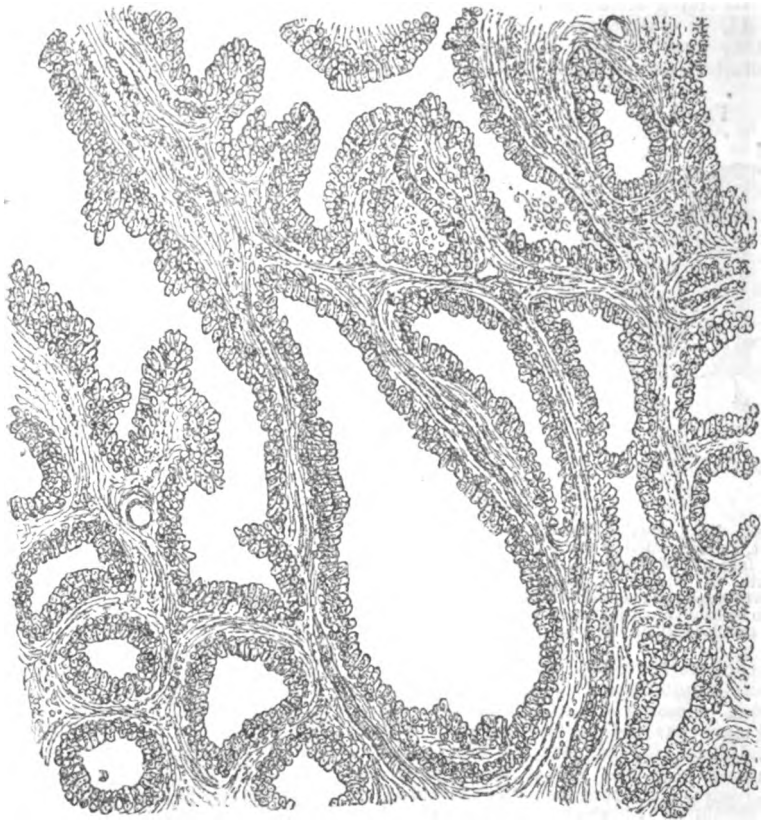
the free surface of the neoplasm line also the wall of its containing cyst. In their microscopic appearances such growths occasionally present some resemblance to alveolar cancer, for certain sections show ovoid spaces containing epithelial cells surrounded by scanty fibrous stroma. These cells, however, differ from cancer cells in that they are of the columnar type, and, instead of being irregularly massed within the alveolar spaces, they are regularly arranged round their walls. The alveolar appearance is produced by cross sections of the epithelial-lined, interpapillary depressions, between the closely packed ramifications of the neoplasm. In certain cases, when the villosities are lined with

FIG. 3.

Villous papilloma of breast under a low power. (Pollard.)

but a single layer of epithelium, a tubular appearance is thus produced.

In the initial stage of their development villous growths present as simple conical or forked outgrowths of the lining membrane of the duct. In this condition such growths are occasionally met with in the ducts in the vicinity of the fully developed growths. Further proof of their origin from this source is to be found in the fact that the cells lining their free surfaces are invariably of the same columnar type



Digitized by Google

as those of the originating ducts. Labbé[2] has recorded a case of multiple villous papillomata in which the free surfaces of the neoplasms and of the containing cyst walls were lined throughout with flattened epithelium. Here the disease was probably of intra-acinous origin. This is the only case of the kind with which I am acquainted.

It will be gathered from the foregoing description that these growths are of a perfectly innocent nature, though often multiple; they have no tendency to local infection, nor do they ever disseminate in the adjacent lymphatic glands or in the system at large, and when completely removed they never recur. Of the patients in my list one was known to be alive and well fourteen years after operation, and others six, three and a half, and three (two cases) years. In a few cases growths of this kind have been found associated with ordinary fibro-adenomata.

Usually the first symptom of villous papilloma to attract attention is the presence of a fluid discharge from the nipple, which persists, and after a time becomes sanious. Even when this is not the initial symptom it generally appears at an early date, and remains throughout a salient feature. In other cases a small pea-sized tumour is the thing first noticed. The presence of a tumour is, however, often overlooked by the patient, as it seldom causes pain or other inconvenience. The disease progresses slowly and almost imperceptibly, so that a surgeon is seldom consulted until it has existed for several years. Of the eighteen cases in my list it was known to have existed for periods of twelve, ten, four, and three years (two cases) before advice was sought. Having maintained this slow rate of increase for some years, these tumours not unfrequently get larger rather rapidly, owing to increase in the fluid contents of the cysts. In two out of my eighteen cases there was history of previous injury; in one the nipple had been severely bitten twenty-two years previously; in the other the disease was first noticed four months after a blow. The patients affected are generally prolific married women, and the right breast is as often the seat of the disease as the left. The average age at onset is forty-three years; the youngest in my list twenty-three, the oldest fifty-five. The numbers for each quinquennial period are as follows:—Twenty to twenty-five years, in 1 case; twenty-five to thirty years, in 1 case; thirty to thirty-five years, in 1 case; thirty-five to forty years, in 5 cases; forty to forty-five years, in 3 cases; forty-five to fifty years, in 2 cases; fifty to fifty-five years, in 2 cases. Villous papillomata therefore develop at a much later period than fibro-adenomata—of which the average age at onset is 30·4 years; but they arise somewhat earlier than cancers, of which the average age at onset is forty-eight years. The disease I have just sketched has hitherto almost invariably been confounded with encephaloid or scirrhous cancer, or sarcoma, and treated like these affections by amputation of the breast, in several cases the axillary glands having been removed as well. It is clearly a mistake to resort to such severe measures when we have to do merely with a solitary villous growth, or even with several such growths confined to a limited area of the gland. In such cases the disease should be excised, together with the containing cyst wall. Several cases illustrate the futility of cutting into these tumours, and of destroying the overlying skin by caustics. The only result of such treatment is to cause them to fungate and to increase rapidly. When the disease is diffuse the whole gland must be extirpated; but even then the overlying skin, including the nipple and areola, may usually be preserved.

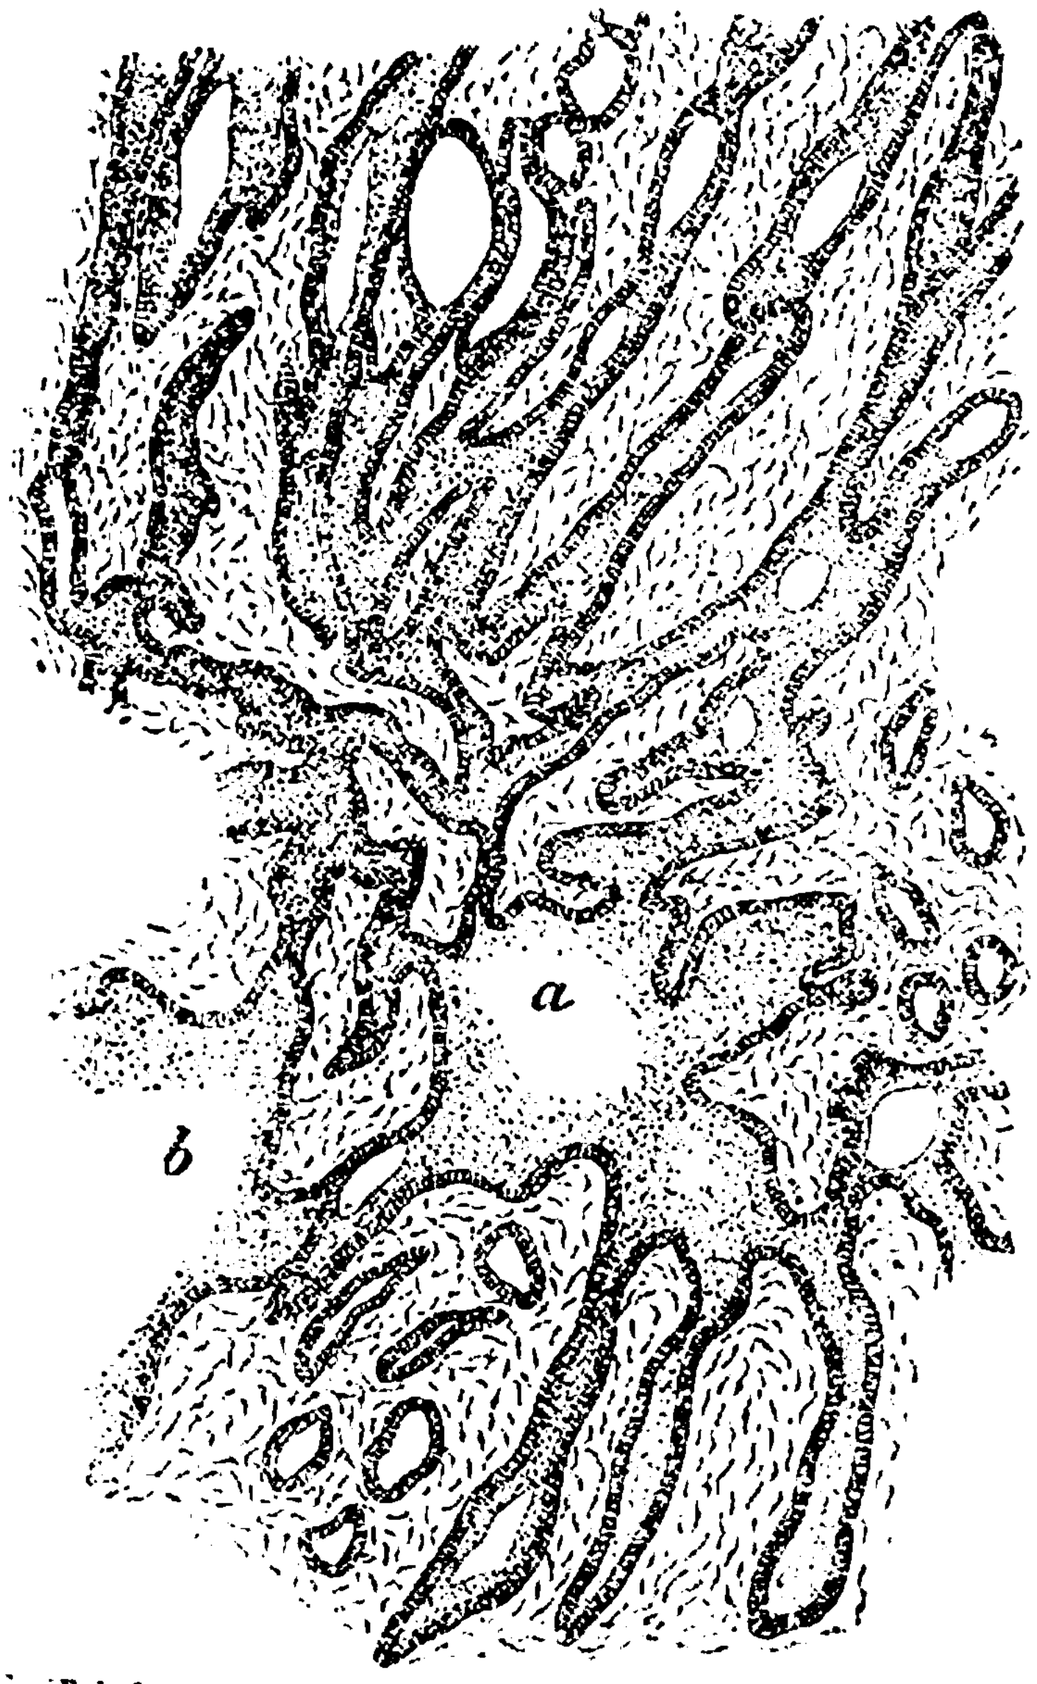
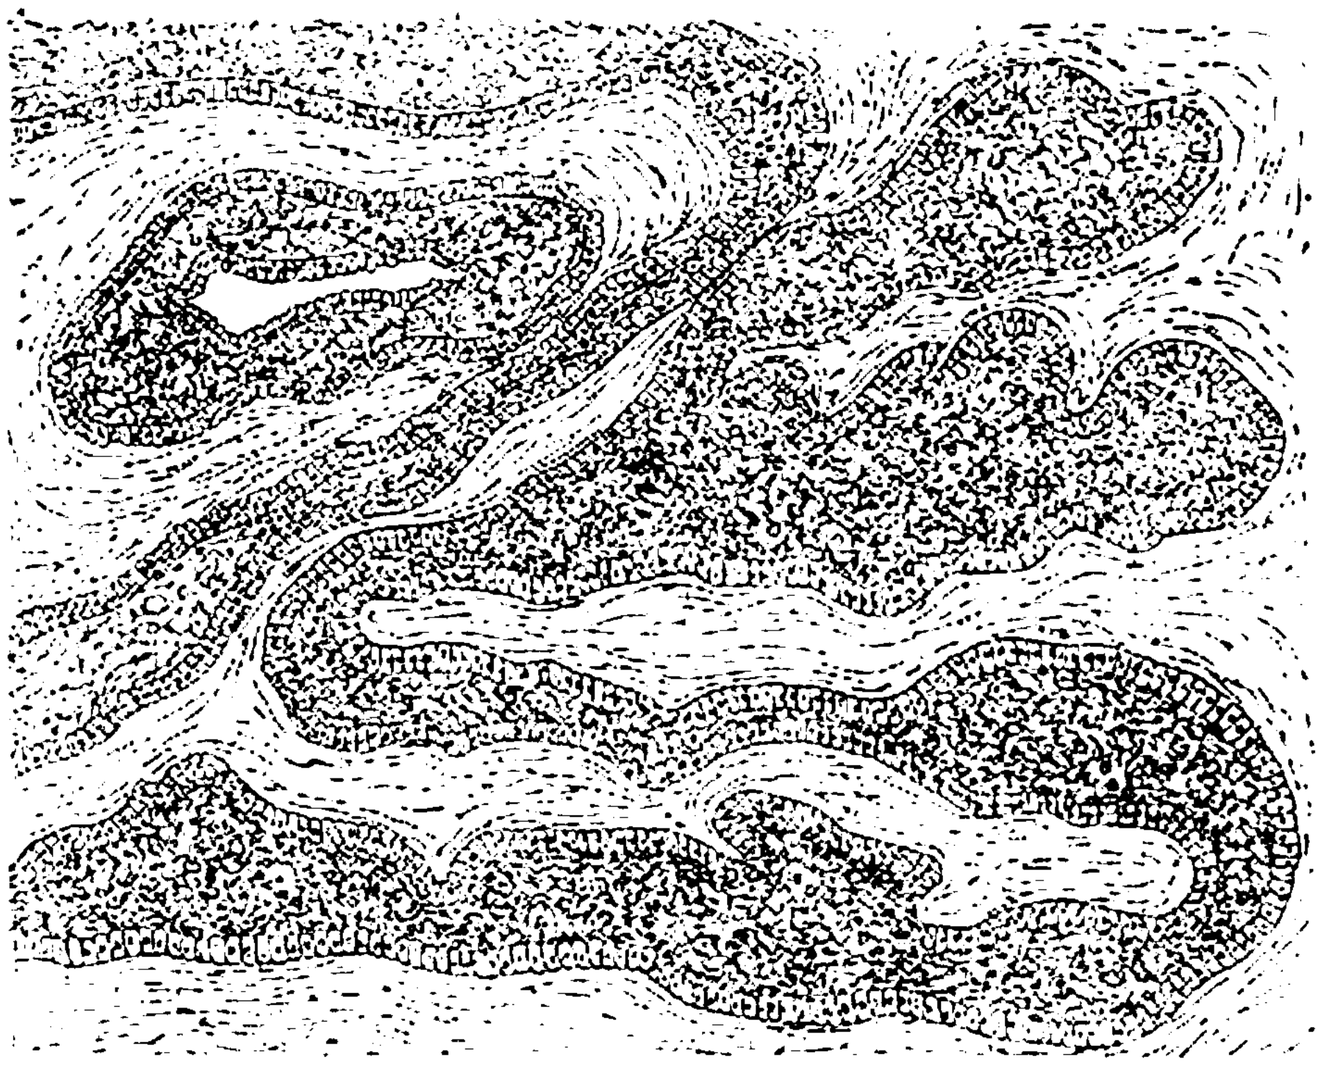
II. TUBULAR CANCER.



The terms "tubular" and "acinous," as applied to mammary cancers, originated with Billroth, but they are used by him in a different sense to what I employ them. According

[2] Traité des Tumeurs Bénignes du Sein, 1876, p. 163.

Digitized by Google



to my views, the great majority of breast cancers—about 96 per cent.—consist entirely, or almost entirely, of structures of the acinous type, the tubular form being quite a rarity. I regard the ordinary scirrhous or alveolar cancer as morphologically of the former type, the alveoli and their contents roughly representing acini in the resting stage. The latter term I restrict to certain cancers—histologically often very duct-like in appearance,—the true duct cancers. These are often associated with cysts and intra-cystic papillary growths, the latter of which never develop in connexion with acinous (scirrhous) cancers.[3] The concurrent testimony of recent observers is against Cornil and Ranvier's statement that villous cancer is merely a form of scirrhus accompanied by intra-cystic villous growths. This form of breast cancer is undoubtedly a distinct variety. Histologically it is characterised by the presence of elongated, intercommunicating, cellular processes, growing into the surrounding connective tissue. (Figs. 5 and 6.) These processes have the form either of hollow tubes (Figs. 5, 7, and 8) lined with one or several layers of columnar epithelium; or of solid cellular cylinders (Figs. 6 and 9), of which at least the peripheral cells are of the columnar type. The appearances seen in cross sections are well shown in Figs. 7, 8, and 9. In connexion with these structures, numerous small cysts frequently arise, through granulo-fatty disintegration of their cells; and within the cysts papillary growths often spring up. From the columnar type of their cells, and from the tubular form assumed by the ingrowths, it may be inferred that these neoplasms originate from the mammary ducts. Neoplasms of this kind generally present as hard, nodulated, irregular tumours, which are usually circumscribed, and often more or less completely encapsuled. They vary in size from a hazel nut to a newly born child's head, and commonly they are as large as a hen's egg. They are generally mobile and very seldom do they cause retraction of the nipple, or of the overlying skin. On section we find them composed of firm, whitish—or, in places, pale pinkish—solid substance, formed by the ingrowing epithelial processes, with here and there yellowish areas out of which pultaceous substance, consisting of epithelial cells in granulo-fatty degeneration, may be squeezed. Embedded in this solid substance are numerous minute cysts. Sometimes the latter are so numerous as to convert the tumour into soft reticular substance. These cysts contain mucoid or pultaceous fluid, and not unfrequently intra-cystic papillary growths. In this connexion ecchymoses and hæmorrhages sometimes arise.

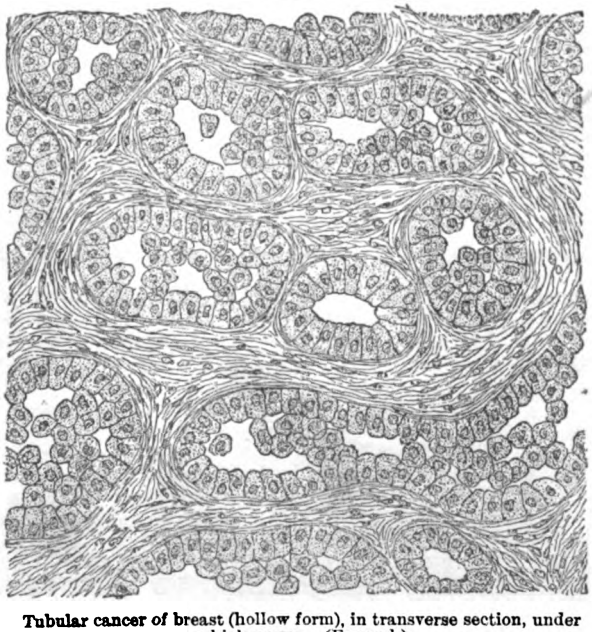
Tubular cancer of breast (hollow form) in transverse section, under a low power. (Bryant.)



Their clinical history is a matter of great interest. The chief points are these:—They occasionally disseminate in the adjacent structures. In a case recorded by Shattock[4]

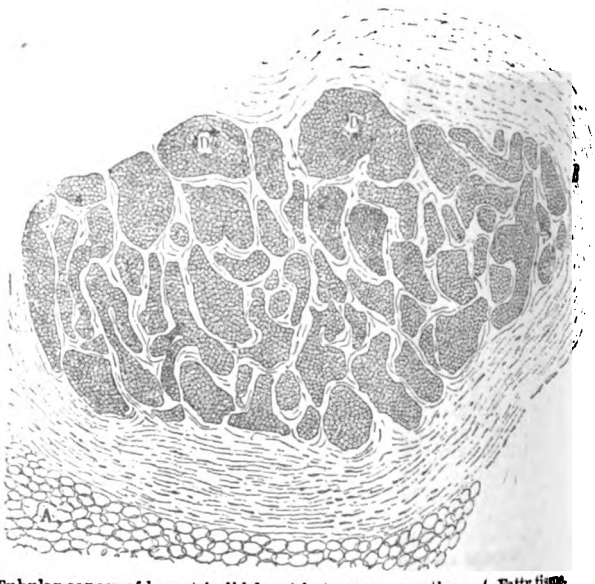
[3] In very exceptional cases villous papilloma and acinous cancer may coexist as independent growths in the same mamma. See Mr. Bowlby's paper (No. 2), St. Bart.'s Hosp. Reports, xxiv., 1888, p. 265; and Mr. Hutchinson's Archives of Surgery, vol. ii., No. 6, Oct. 1890, plate xxv., fig. 2.

[4] Trans. Path. Soc. Lond., 1888, p. 324.

nodules of this kind were found adherent to the two upper ribs in a woman aged sixty, who died a few weeks after amputation of the breast for the primary disease. The chief evidence of their malignancy is, however, to be found in the frequency with which they recur locally after removal. This is known to have occurred in eight out of my eighteen cases. The most striking of these is Butlin's. His patient was a married woman, aged sixty-four, the mother of several children. Six months before coming under treatment she first noticed a lump the size of a hazel nut in her left breast. When first seen she had a tumour the size of a bantam's egg, below and external to the left nipple. It was firm, irregular, and not adherent to the overlying skin, neither did it cause retraction of the nipple. The axillary glands were normal. The breast was extirpated, together with the tumour, which was circumscribed and invested with a thin capsule. It was of brownish-black colour and friable consistence. Two years later she returned with a recurrent tumour, the size of a walnut, at the axillary end of the scar. It was freely excised, and presented the same appearance as the primary disease. One year and a half later she came under observation again with several recurrent nodules in the same situation. They were of a year's growth. These were freely excised, together with the surrounding tissues. They presented the same circumscribed outline and brownish-black colour as the former tumours. Two years and nine months later two fresh

FIG. 8.

Tubular cancer of breast (hollow form), in transverse section, under a high power. (Formad.)



recurrent tumours, of some months' duration, were excised from beneath the old scar. Their structure precisely resembled that of their predecessors. The axillary glands were never affected, nor was there any sign of dissemination of the disease in any part of the body. The general health remained unimpaired.[5]

The adjacent axillary lymph glands are occasionally infected by these neoplasms. This occurred in five out of my eighteen cases. Godlee's is a typical case.[6] His patient was a childless widow, aged sixty-three, who when first seen had a mammary tumour of four months' duration. It was destroyed by caustic. Three or four months later it recurred in the scar. A year later a small lump was first noticed in the axilla, which in the course of another year had grown into a hard rounded tumour two inches in diameter, and the overlying skin was adherent and red. The breast was amputated, and the axillary tumour was dissected out. On dissection, the mammary tumour was found to be enclosed in a dense fibrous capsule, which contained a considerable quantity of solid dark-brown substance, like modified blood-clot, and about two drachms of dark treacle-like blood. The axillary tumour was of similar nature, only it contained less blood. It was described as "an anomalous form of blood cyst." On placing the tumour in water, it was seen to consist of a number of tortuous processes. After hardening it was very friable, and difficult to cut sections off, as these tended to fall to powder. On microscopical examination, there was revealed a scanty fibrillar tissue uniting together a number of tubules, lined by several layers of hexagonal epithelium.

To account for the comparative rarity of lymph gland dissemination, Labbé and Coyne have pointed out that between the proliferating epithelial zone and the nearest lymphatic lacunæ a barrier of thick fibrous tissue exists (*Fig. 9*), which must be overcome before the cancer cells can gain entrance into the lymphatics. The slowness with which this is overcome indicates, I take it, the low degree of malignancy of the new growth, rather than of the strength of the intervening barrier. Some authors have stated that these neoplasms cause also general systemic dissemination; but I know of no case that can be cited in support of this assertion.

The first symptom of tubular cancer usually is the presence of a small tumour in the central part of the

FIG. 9.

Tubular cancer of breast (solid form) in transverse section. *A*, Fatty tissue. *B*, Fibrous capsule. *D*, Epithelial cylinder. (Labbé and Coyne.)

breast, beneath the nipple or areola. Discharge from the nipple is seldom experienced. Tubular cancers increase much more rapidly than villous papillomas; in less than a year they commonly attain the size of a hen's egg. Occasionally they burst through the overlying skin and fungate. In my list there are four cases of this form of cancer in which tumours had been present for long periods—viz., thirty-six, eighteen, fifteen, and seven years respectively. In each of these cases a small tumour had existed for most of the time—whose increase was almost imperceptible—and then during the last few years it had rapidly attained large size. There are several facts about the history of these cases that make me think we here have to do with tubular cancer supervening on villous papilloma of many years' standing. The following is a typical case by Labbé and Coyne.[7] A well-nourished, healthy-looking woman, aged sixty-seven, four years after her only confinement, which was forty years ago, first noticed a small movable tumour in the inner part of her left breast. She had at this time and for two years subsequently serosanious discharge from the nipple, which then ceased spon-

[5] In answer to a letter of inquiry, Mr. Butlin has kindly informed me that he last saw this patient in June, 1889, two years and a half after the last operation. "She then had a small dark tumour below the scar, towards the axilla, and one or two hard enlarged glands in the axilla."

Digitized by Google

taneously. After this the tumour got larger, then it remained nearly stationary for thirty-three years. At the end of this time it was the size of a small egg. Soon afterwards, without any obvious cause, it began to increase rapidly, and quickly invaded the whole breast. In the course of three years a hard nodulated tumour, the size of a man's two fists, had developed. The nipple was buried in the growth, but not retracted; nor was the overlying skin adherent. Some of the bosses fluctuated. Nothing is said about the condition of the axillary glands. The diseased part was amputated. On examination after removal, the tumour was found to be encapsuled. In addition to the large lobulations and bosses, its surface was thickly studded with small rounded projections. On section its central part consisted of whitish compact lobular structure, and its periphery was occupied by numerous small cysts containing papillary growths and brownish fluid. Microscopical examination of the solid basis of the tumour showed numerous elongated, tortuous, anastomosing cylinders of epithelial cells growing in scanty fibrous stroma. The peripheral cells of these ingrowing processes were regularly arranged and columnar, those within were of irregular shape, and in various stages of granulo-fatty degeneration.

Tubular cancer supervenes at a much later period of life than villous papilloma, and even than acinous (alveolar) cancer. The average age of my cases at the outset of the disease was 53·5 years; the oldest 65·5, the youngest forty. The numbers for each quinquennial period are as follows: Forty to forty-five years in 4 cases; forty-five to fifty years in 3 cases; fifty to fifty-five years in 2 cases; fifty-five to sixty years in 4 cases; sixty to sixty-five years in 5 cases; sixty-five to seventy years in 1 case. The only treatment of any avail is free amputation of the affected part, as for scirrhous cancer; but the axillary glands need not be interfered with unless obviously diseased.

I only made the acquaintance of Brodie's lecture on "Sero-cystic Tumours of the Female Breast" after the above had been written. He is evidently the first who recognised the true nature of the disease. Honour to him! It is, indeed, impossible not to be struck with admiration at the singularly clear and penetrating insight into this obscure disease which this distinguished man had attained, and that without the microscope and other modern aids.

NOTE ON CONCUSSION OF THE SPINAL CORD.

BY J. A. MACDOUGALL, M.D., F.R.C.S. EDIN.,
FORMERLY SURGEON TO THE CUMBERLAND INFIRMARY.

As a small contribution to the literature of concussion of the spinal cord, and as emphasising the interest attaching to such cases as the one that appeared in THE LANCET of Oct. 24th, 1891, p. 928, reported by Mr. Clutton, I think the following worth recording.

A. C——, aged forty, a goods guard, while attending to the lamp attached to the rear of his van, his train being in motion, lost his balance and fell backwards into the ballast way. He had no loss of consciousness, for he at once discovered that his legs were paralysed, and concluded that he had "broken his back." Some hours later he was admitted into the Cumberland Infirmary, and when I saw him I found him to be a tall, muscular, and very intelligent man, making no complaint beyond that of his powerless limbs. On examination of his back there was seen to be in the central line a considerable localised bruising over the lowest dorsal and upper lumbar spines, attended by marked tenderness, but there was no evidence of any injury to the spinal column. This, I need hardly add, was very carefully sought for. His legs were absolutely paralysed. Under his utmost efforts there was no evidence of muscular movement in them. Sensation was distinctly impaired. The bladder was distended and required relief by the catheter, the bowels were constipated, his temperature was subnormal, and his pulse feeble, but quiet. His consciousness and the recollection of his accident were perfect. For two days after his admission there was no evidence of improvement in mobility, but sensation returned somewhat rapidly. On the third day he could move his ankles and toes, and could very feebly and slowly draw up his legs, while the bladder was beginning to regain its expulsive power; and at the end of a week he could, while resting in bed, move his limbs freely, and the use of the catheter was no longer necessary. Sensation was then fully re-established. His temperature, normal on the day following his accident, never rose above 99·4°, and this only for two days.[1] Three weeks after his admission he was allowed out of bed, when it was found that although he could stand firmly, his power of walking was feeble and unsteady. Six weeks after his accident, and when with the aid of a stick he could move about with comparative freedom, he was made an out-patient, his statement then being that walking greatly fatigued him, and that extra effort in this way was always followed by stiffness, weariness, and numbness in the legs. His limbs were, however, not wasted, their muscular tonicity was fairly good and their sensations quite normal. Two months later he ceased his attendance, and when, a year or two afterwards, I had an opportunity of examining him I found him in perfect health, his story being that he was then as vigorous as in his earlier days.

A good many years have passed since then, and the case, at least as regards its completeness, remains with me as a solitary experience. I regarded it—rare as I ventured to believe such cases to be—as one of spinal concussion without simultaneous injury to the spinal column; but what the conditions were that underlay its symptoms remained matter of conjecture. A short time ago, and in quite another field of observation, I believe I found for them a probable explanation, and thus: A good stag was stalked to within eighty yards, and aim was taken at the upper part of his neck. He sank instantly to the shot, and the keeper, running in, divided freely the vessels of the throat. On introducing my finger into the bullet wound I found that it had been placed a little higher than was intended, that it had passed transversely through the muscles of the nape, and that in its passage it had but fractured the upper part of a vertebral spinous process. At once the thought occurred that the sudden collapse of the animal was due to damage to the spinal cord, and I therefore had the parts carefully removed for dissection. On clearing the vertebral column I found one spinous process alone injured, about half of which had been carried away; this, however, so cleanly that there was no marked fissuring of the portion that remained. The body of the injured vertebra was intact, as were those on each side of it, and the ligamentous structures were unharmed. Removal of the laminæ demonstrated more fully the perfect solidity of the column and the fact that there was no effusion without, or injury to the spinal theca. The subarachnoid space was also free, but it was noticed that there was a considerable effusion of blood in the meshes of the pia mater in a direct line with the fractured spinous process. About three inches of the cord were removed for examination, and this was done by the cutting of thin transverse sections. When the portion of it which lay within the body of the damaged vertebra was reached, it was found to be the seat of numerous points of very minute ecchymoses which were scattered through its substance, and that at one or two points there existed disseminated specks of extravasated blood. Its texture was, however, quite firm, and neither under pressure nor when exposed to a stream of water was it found to be markedly softer or more diffluent than the bit of normal cord with which it was compared. Unfortunately,

[1] That no reference is made to the condition of the reflexes is explained by the fact that the case occurred anterior to the published researches of Erb and of Westphal.

Digitized by Google

the examination was entirely macroscopic, neither a microscope nor the means for preserving and hardening the specimen being available. This is matter for regret, as it is possible that the existing lesions were not confined to the walls of the bloodvessels.

These two cases seem to me to supplement one another, and although it is as a rule unwise to generalise from single examples, we know so much of the symptomatology and of the morbid appearances that indicate cerebral concussion that we could well anticipate similar conditions in a corresponding injury to the spinal cord. In both events the spinal column was subjected to sudden and severe jar, and in both with a very similar and striking result. Admitting that the injury in the instance of the stag was an exceptionally severe one (for the contusing power of a ball travelling at a high rate of velocity is fully recognised), still in the case of A. C—— there were certain circumstances which tended to render the blow he received one of great severity. He fell backwards from a train moving at fair speed in the opposite direction, receiving thus a considerable impulse; and when thus impelled he probably struck, judging from the localised nature of the bruise found, upon a projecting surface. Such conditions must have caused a sudden and severe stroke, and probably produced in him similar lesions to, but slighter than, those found in the stag.

Mr. Page, in his masterly and most valuable work upon "Injuries of the Spine and Spinal Cord," p. 19, refers to a case recorded by Dr. J. Liddell, in which a Minié ball striking a man to the left of the second lumbar vertebra and emerging some inches to the right fractured in its passage its spinous process. Paraplegia and paralysis of the bladder were at once developed, but at the end of two months were being gradually recovered from. In this instance the circumstances which gave rise to the injury were identical with those which occurred in the case of the stag, and I take it that the symptoms developed in the man owed their origin to such lesions in the spinal cord as were found to exist in that of the animal. Here, however, I would state my belief that even in the spinal cord we may have symptoms of a passing "concussion" in which probably the stroke being less severe, the harm actually done is neither so marked nor so grave. My reason for thinking this is that I have known a deer shot in the neck fall instantly and lie apparently dead for some little time, but, when approached, gather itself up with a visible effort and go off at sufficient speed to lead to its escape. In it, I imagine, the ball passed immediately over the spinal column without perhaps actually injuring it, but sufficiently close to communicate to it such a jar as for the time being inhibited the action of the organ it contained. What seems to render this more probable is the fact that a ball striking some other and non-vital part beyond, producing the sound of impact and the flight of the deer, would have afforded no immediate evidence of injury.[2] Even, however, in these lighter shocks—these so-called "concussions"—there is probably always a marked lesion existing. That this is usually so necropsies in fatal cases of cerebral concussion reveal to us, and in these the appearances found are precisely those which I have described as occurring in the spinal cord I examined. They are the coarse evidence of the jar the nervous mass has sustained, and the violence of which, so far as the naked eye carries us, seems to fall largely upon its vascular apparatus. Whether this be due, as Duret holds, to the result of force communicated to the cerebro-spinal fluid and its effects in the peri-vascular spaces, or to the vibratory thrill imparted to the mass itself, matters little; in either case what occurs is an apparently temporary, though happily incomplete, suspension of its essentially vital action. That this is the direct issue of the shake, and is independent of such vascular lesions as post-mortem examination reveals, is, I consider, probable; for although these mark well and emphatically the severity and nature of the injury sustained, they are, as a rule, insufficient *per se* to have produced a fatal result. That such lesions exist to a greater or less extent in all cases of cerebral and spinal concussion which do not die wellnigh instantaneously is my belief, and they write the record that the notable disturbance of function observed depends upon *organic* injury. I have some doubt, however, that such evidence can never be absent, and it comes from the observation of cases of cerebral concussion seen at the moment the injury was received. I vividly remember the case of one man—certainly the most striking in my experience—whom I saw fall from a height of some fourteen feet and alight upon his vertex in the hard roadway. The appearance he presented was very impressive: the terrible pallor of his face, the dropped jaw, the fixed pupil and insensitive eye, the arrested breathing, and the absence of all pulse at the wrist, made me believe he was dead. It was only when, having bared his chest and put my ear over his heart, I could detect such far away and feeble sounds as mark generally a rapidly ebbing life that I recognised that vitality was not quite extinct. Under the use of stimulants applied chiefly externally he slowly rallied, and ultimately recovered. But my reflection was this: Suppose that man had died—as in the presence of a heart with feeble walls or one less stable in its ennervation, and in the absence of help, he probably would,—what then would have been the appearances presented by his brain? If, as the experiments of the most recent observers seem to show, a primary anæmia from arterial spasm, the result of a powerful peripheral irritation, be the primary step in the development of the phenomena of concussion, and a congestive stage the sequel to this, it is, I think, probable that the blood extravasations so generally found can only occur after vascular relaxation; and that, if cerebral shock be immediately fatal, a singularly pale brain with great turgidity of its veins may alone indicate the mode of dying. Such a belief is contrary to the teaching of the highest authorities, and it may be groundless; but it is just possible that it may explain the absence of all coarse cerebral lesions in certain cases, attached to the records of which are the names of generally reliable observers.

The occurrence of concussion of the brain, apart from marked injury to its bony case, has always been admitted, but it has been notably otherwise with concussion of the spinal cord. The experience which prompts this note proves, I think, that such an injury may occur without important structural injury of the vertebral column, that it is the result of severe and direct injury, that its symptoms are at once apparent, and that when they are present there is some easily recognisable lesion producing them. The further teaching is this, that the treatment of such cases should be that usually followed in those of cerebral concussions, the main indications being the pursuit of such measures primarily as will prevent the further effusion of blood from ruptured vessels, the prompt relief of that state of active congestion which, as in cases of cerebral concussion, may possibly supervene, and the allowance of such a period of rest as will enable nature to repair the important injuries the cord has certainly sustained.

Cannes, France.

[2] In this reasoning I am not forgetful of the "knock-down blow" from general shock, familiar alike to the army surgeon and to the sportsman, which is apt to follow the blow of a missile, but where the recovery is, as a rule, rapid.

A SUCCESSFUL CASE OF

ILEO-SIGMOIDOSTOMY (SENN'S METHOD) FOR INTESTINAL OBSTRUCTION DUE TO MALIGNANT DISEASE OF THE HEPATIC FLEXURE OF THE COLON;

WITH SOME REMARKS ON INTESTINAL ANASTOMOSIS AND A DESCRIPTION OF A MODIFICATION OF SENN'S BONE PLATES.[1]

BY H. LITTLEWOOD, F.R.C.S.,
HON. ASSISTANT SURGEON TO THE GENERAL INFIRMARY AT LEEDS.

THE following are the notes of the case: G. F——, aged thirty-five, was admitted to the Leeds Infirmary on March 17th, 1891, under the care of Mr. W. H. Brown, with marked symptoms of intestinal obstruction. The patient said that since Christmas he had had a good deal of pain in the right iliac region, and for the last three weeks he had been unable to work. Three days before admission vomiting commenced, and continued at intervals; no motion or flatus was passed during this interval. On admission the patient was very ill, suffering from severe spasmodic attacks of abdominal pain and frequent vomiting. The abdomen was distended. The intestines could be seen distended and

[1] Paper read before the Leeds and West Riding Medico-Chirurgical Society on Dec. 4th, 1891.

Digitized by Google

moving beneath the abdominal wall. The whole of the right side of the hypogastrium was dull. Before admission the patient had a small dose of morphia. Soon after admission the bowels were well opened. An enema was given, followed by another good evacuation. After this the patient was much better, vomiting and pain ceased. He left the infirmary on March 17th.

He was admitted again on Aug. 14th with well-marked intestinal obstruction. At no time since leaving the infirmary had he felt really well. He had had occasional attacks of vomiting and constipation, often complaining of pain after food. He had seldom been able to work more than two or three days at a time. Latterly the attacks had increased in frequency and severity. The bowels had not been opened for the past five days; he passed flatus a few times during this period, and vomited frequently. On admission the following note was made:—"Patient looking very ill; not much collapsed. Temperature 98·4°; pulse 100. Abdomen distended; resonant. Except low down in the flanks, coils of distended intestine can be easily seen moving (sometimes violently) through the abdominal parietes at frequent intervals. The movements can be easily excited on palpating the abdomen. No tumour can be seen or felt in any part of the abdomen. Complains of a griping intermittent pain, radiating all over the abdomen. Between the attacks of pain there is merely a feeling of distension." Since admission he has vomited several times; the vomit has not been feculent at any time. He has not passed any blood or pus per anum. Nothing felt by rectal examination. Soon after admission I saw the case with Mr. W. H. Brown, under whose care the patient had been admitted, and we agreed that as enemata had answered so well on a former occasion they should again be tried. Mr. Brown, going away the next day, handed the case over to my charge. A gravitation enema of a pint of warm olive oil was given; this was soon followed by a good evacuation, after this a simple enema was given, with good results.—Aug. 15th: Feels much more comfortable; pain and distension much less; vomiting has ceased.—19th: Has been feeling more comfortable; still some distension of abdomen. No vomiting; bowels opened by enemata.—23rd: During last few days patient has not been quite so comfortable. Some feeling of nausea; bowels opened by enemata. Abdomen still distended; patient has a feeling of general abdominal discomfort. Sometimes movements of the bowels can be seen, and to-day can be easily excited by abdominal palpation. At a consultation with the majority of the surgical staff the general opinion expressed was that the case was one of intestinal obstruction due to malignant disease of the colon, probably at the upper part of the sigmoid flexure. Abdominal exploration was advised, with a view of removing the growth if possible; if not, to stitch the bowel above the obstruction to a part of the collapsed bowel below.—24th: The patient being under the influence of ether, with the assistance of Mr. Moynihan, the resident surgical officer, I operated by making an incision three inches long in the middle line between the umbilicus and pubes, going through the edge of the right rectus. All bleeding having been stopped, the peritoneal cavity was opened to the same extent. There was some fluid in the peritoneal cavity. The small intestines were very much distended, some parts of the ileum being as much as two inches in diameter. They were injected. Cæcum and ascending colon distended. Transverse, descending colon, and sigmoid flexure collapsed. A large mass of growth about the size of an orange was found situated in the hepatic flexure and fixed. Mr. Mayo Robson, who was present at the operation, after having examined, agreed with me as to the inadvisability of attempting removal, and thought with me the best plan of treating the case would be to stitch the lower part of the ileum to the upper part of the sigmoid flexure. This I did by first pulling a loop of ileum out of the abdominal wound, emptying it of its contents, then surrounded it with a piece of indiarubber tubing. The same was done to a loop of sigmoid flexure. An incision about one inch long was made in the convex surface of each. Senn's decalcified bone-plates were inserted, and secured in the usual way. Four extra silk sutures were then put in round the margin of the plate, on the convex surface of the two pieces of bowel, to give a little extra security. The bowels were then replaced in the abdominal cavity, the cavity carefully wiped out, and the abdominal wound stitched up in three layers—peritoneum, muscles and fascia, and skin.—26th: Patient feels very well. Has passed flatus; no vomiting; temperature normal; less distension of abdomen.—28th: Patient still feels very well. Had bowels moved to-day. Sits up in bed.—Sept. 1st: Has improved since last note. Dressed to-day, wound quite healed; no distension of the abdomen. One of the bone-plates has passed per anum to-day.—5th: Still improving; bowels acting regularly.—7th: Patient feels very well; has been up to-day—i.e., fourteen days after operation.—10th: Improvement maintained; appetite good.—12th: Says he feels perfectly well.—16th: Left infirmary to-day—i.e., twenty-three days after operation. Temperature 100·2° on the mornings of the 25th and 26th. Temperature 99·4° on the evening of the 27th, and after that normal.

Diet.—For the first five or six days after the operation he was fed chiefly on milk and Benger's food. Had fish on Aug. 31st, chicken on Sept. 3rd, chop on Sept. 4th, ordinary diet on Sept. 7th. Patient was shown at the meeting of the Leeds and West Riding Medico-Chirurgical Society on Oct. 9th; was apparently very comfortable; no abdominal distension; bowels opened every day. A few days after this he went to work as a miner.

The case described above is an additional demonstration

FIG. 1.

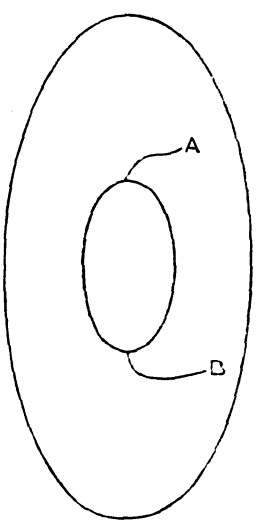

FIG. 2.

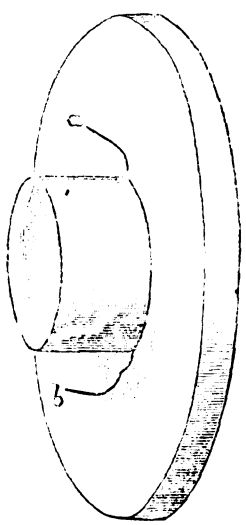

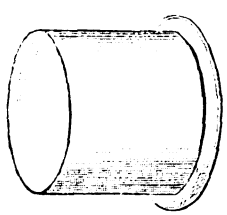

FIG. 3.

to the cases already recorded of the possibility of treating intestinal obstruction by establishing a communication between the distended bowel above the obstruction and the collapsed bowel below, and so cutting off the obstructing portion from the intestinal tract. We owe to Senn an enormous debt for this great advance in the treatment of intestinal obstruction, and, considering his paper was read in September, 1887, at the International Medical Congress at Washington, it is very remarkable that up to the present time only four cases have been recorded of this method having been used for the treatment of intestinal obstruction. Two were performed by Senn, one by Mr. F. B. Jessett, and the other by Mr. Reeves. They are referred to in a letter by Mr. Jessett in THE LANCET of Feb. 21st, 1891. Similar operations have been performed for other causes in several cases—e.g., injuries, pyloric obstruction, &c. This case differs somewhat from the other recorded cases in that the intestine was not divided, but a simple lateral anastomosis made. In Senn's two cases the growth was

Digitized by Google

first excised; in the other two the operation of lateral implantation was performed; all of them necessitating a division of the intestine.

Before we were acquainted with this method, the treatment of cases of intestinal obstruction requiring surgical interference might have been arranged into three classes:—1. Those in which some definite obstruction was found and was relieved by operation. 2 Cases in which the obstruction was found and could not be removed, an artificial anus being made. 3. Cases in which, after a prolonged search, either the obstruction was or was not found, the patient dying of shock. It is for the treatment of such cases as occur in Classes 2 and 3 that Senn's method offers such advantages. In Class 2 the artificial anus is obviated. In cases belonging to Class 3, if the obstruction cannot be found after a reasonable time has been expended in the search, then lateral anastomosis offers the best chances of a successful termination. From assisting at a large number of cases of abdominal sections, it has always struck me that time is a very important element in the success of a case. By this method there is a great saving of time. With a little practice on the cadaver, or having seen or assisted at the operation, it can very quickly be performed (in about ten or fifteen minutes). I have ventured to suggest a modification of Senn's plates, with the idea of (1) doing away with the four stitches attached to the upper and lower margins of the apertures of the plates, which perforate the whole thickness of the intestinal walls; (2) of performing the operation more quickly; (3) of ensuring a good opening between the two pieces of intestine. The plates have been made for me by Messrs. Maw, Son, and Thompson; the accompanying drawing is by Mr. Haigh. The suggested modification is to fix a tube of decalcified bone (Fig. 3) into the aperture of one of the plates (Fig. 2). This should be made to accurately fit into the aperture of the other (Fig. 1); by this method the two plates could be held together, and the two parts of the intestinal walls between them brought evenly into contact with each other. It might be well to have a piece of fine silk attached to each of the ends of the apertures (as marked A a, B b in Figs. 1 and 2), so that by tying A a and B b together greater security would be made. The intestinal walls around the margins of the plates should be attached by a few sutures.

In a very interesting paper by Dr. Halsted of Baltimore a method of lateral apposition by sutures is described. He insists very strongly on the importance of including some of the submucous layer of the intestinal wall in these and all suturing operations of the intestine. I am sure it is very important to recognise this observation, but cannot help thinking the bone plates will have the advantage over any method of suturing, owing to their simplicity and the time saved in using them.

Leeds.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

THE NASO-PHARYNX IN INFLUENZA.

BY ARTHUR E. NEVINS, F.R.C.S. EDIN.

SINCE the influenza appeared in Europe a couple of years ago there have been abundant opportunities for everyone to become acquainted with the symptoms peculiar to this disease, and it has been generally recognised that catarrh of the nasal passages, with a more or less free evacuation of mucous, is a very common symptom. Many cases, however, come under observation in which there is comparatively little mucous discharge from the nose. But in these cases also there is always, so far as my observations go, a severe inflammation of the whole mucous lining of the naso-pharynx, which is often more intense, and productive of more acute distress to the patient than in the cases in which the catarrhal symptoms are more obvious. It seems, in fact, as if it was a rule, almost without an exception, that in influenza the infection first attacks the naso-pharynx, and it is the intense inflammation of this mucous membrane (which, when all its ramifications through the ethmoidal and frontal sinuses are taken into account, represents a very large superficial area) that is the cause of the intense debility and grave constitutional disturbances that ultimately supervene. The shock to the system is quite comparable to that of an extensive burn or a rapidly spreading attack of erysipelas. The appearance of the tonsils and pharynx in many cases quite bears out this idea, for the mucous membrane is seen to be of a deep red colour, rather dry, and from its puffiness suggestive of subjacent cellulitis. Nasal respiration is impeded, and there is a heavy, unpleasant smell, which is very perceptible to the patient, and also to those about him.

The intense cardiac and general enfeeblement which accompanies a "hospital throat" is well known; to many members of the profession it has been a painful personal experience. The prostration in cases of influenza is very similar in character, and probably dependent upon the same cause. If this is the case, it would lead us to look to local remedies, applied to the inflamed naso-pharyngeal mucous membrane, as likely to be efficacious in treating the general condition. The object of the present note is to describe a simple line of treatment, based upon a belief in this theory, which has been singularly successful in every case of influenza that has come under my own observation; furthermore, I can testify from personal experience to the immediate relief which it gives to the headache, feverishness, rigors, and other discomforts of the acute stage of an attack. It consists of spraying the nostrils and throat with a lotion composed of four grains of chlorate of potassium, four minims of tincture of perchloride of iron, to one ounce of peppermint water. The patient leans his head well back, and the spray is sent up one nostril until it can be felt trickling into the throat. In about twenty to thirty seconds a free expectoration of tenacious, viscid mucus takes place. The other nostril is similarly treated, and then the throat is sprayed. While this is being done the patient should inhale deeply, as by that means the spray is carried down into the larynx and trachea, which is important, as these parts are often affected by the inflammation. The relief and comfort which immediately follow the application is remarkable, and decrease in the fever is soon noticeable. The patient is able to take some liquid food without retching after it, and as a rule sleep soon follows. If the treatment is repeated at intervals of two hours for the first twelve hours, and of four hours during the next twelve hours, it will be usually found that the temperature is by that time nearly normal, and that convalescence has fairly commenced. As regards general treatment nothing need be said here; it must be adapted to the special circumstances of each case. There are, however, two lines of treatment which should in most cases be avoided. Inasmuch as intense cardiac enfeeblement is very common in these cases, the antipyretic drugs, which are all powerful cardiac depressants, are contra-indicated. As a rule, purgatives also are undesirable, for it is very common to find some degree of inflammation of the cæcum or colon as a complication in these cases. Hot applications to the abdomen are much more beneficial, as a rule. In conclusion, it may be well to mention that if a spraying apparatus is not at hand, the same effect can be got by pouring about twenty drops of the lotion up the nostril with a teaspoon and making the patient gargle the throat afterwards, but the spray is the more comfortable mode of application.

Hanley, Staffs.

NOTE ON PRICKLY HEAT.

BY J. A. WETHERELL, M.D.

UNDER the term "lichen tropicus" must be embraced three primary lesions, in frequency taking the following order:—1. A vesicular eruption, the vesicle, of the size of a pin's head, elevated on a roseolous, inflammatory base, being filled with colourless perspiration; sometimes arranged in segments of rings, at others diffusedly spread. On a superficial examination, it resembles much the efflorescence of measles or scarlatina, and occurs principally on the nape of the neck, the flexor surfaces of the forearms and legs, and the front of the abdomen. Even habitants for many years of semi-tropical regions are apt to exhibit this form, especially those who wear woollen underclothing. 2. A wheal with a red surrounding halo, accompanied by intense itching,

Digitized by Google

which induces the sufferer to scratch off the covering cuticle, causing the erythematous effusion to develop a blood-scab. Its characteristics are shown on the backs of the hands and about the ankles, and may be mistaken for mosquito bites. 3. A copper-coloured papule of largish dimensions, on whose surface after twelve hours may or may not appear a pustule. The front of the thorax exhibits this best. The older pathology which regarded prickly heat (lichen tropicus) as a papular eruption, and the more recent, as vesicular—hence termed "miliaria papulosa"—are both partially correct, but also erroneous, inasmuch as they recognise a single lesion. The treatment of all consists in washing the affected parts frequently with superfatted menthol, eucalyptol, or phenol (20 per cent.) soap, allowing the rubbed-in foam to dry, then mopping on with a soft linen rag this lotion: liquor plumbi subacetatis, liquor carbonis detergens, and glycerine, of each one ounce; rectified spirit of wine, three drachms; oxide of zinc, two drachms, to a pint of water; or smearing with the following ointment: vaseline, two drachms; lanoline, two ounces; liquor carbonis detergens, two drachms; oxide of zinc, one drachm; menthol, twenty grains. If of limited extent, a bismuth and zinc powder may replace these. Cotton underclothing should be adopted and frequently changed.

Bunbury, Western Australia.

FORCEPS AS AN AID TO VERSION.

By W. HENRY HARRIS, L.R.C.P.ED. &c.

A CASE I was called to at a long distance by two medical men in attendance in Manitoba may not be without interest. On arrival, I found the patient, aged twenty, in labour, then some twenty hours; primipara; seven months. On examination I found the right arm protruding (had been so some hours, the patient having been kept under chloroform), the right shoulder firmly jammed, and constant powerful uterine contractions, so that the introduction of the hand for version seemed impossible. It occurred to me that if I could apply the forceps (Simpson's long) on the thorax at a point a little below its greatest diameter, gentle pressure would cause the blades to descend towards the pelvis, and so convert the presentation into an ordinary breech. The result was as I anticipated. In this case the fœtus had been dead some hours and the labour premature. My reason for publishing this case in THE LANCET is that I do not see "forceps as a means of version" quoted in the text-books, as well as to suggest that similar means might be applicable in cases where such an unfortunate presentation has occurred.

GUY'S HOSPITAL.

FRACTURE AND DISLOCATION OF THE PELVIS; INTRA-PERITONEAL RUPTURE OF THE BLADDER; PNEUMONIA; DEATH.

(Under the care of Mr. W. ARBUTHNOT LANE.)

THE amount of force required to produce a fracture of the pelvis to the extent described in this case is very considerable. We may remind our readers of the experiments to determine this question recently made by Dr. Areilza which we published in THE LANCET of April 2nd. Intra-peritoneal rupture of the bladder is not by any means a common complication in these fractures, injuries of other parts of the urinary tract much more frequently requiring surgical interference for their relief. It is difficult to say how long after it has occurred a rent in the bladder wall may be successfully sutured. Clinical records prove that the peritoneum is much more tolerant of healthy urine than was at one time supposed; and in the cases treated by Drs. Schramm and Knight, as much as fifty and fifty-four hours had elapsed before an operation was performed, after which recovery ensued. This case is an interesting and important one.

A. F——, aged thirty-seven, a coalheaver, was admitted into Guy's Hospital shortly after 4 P.M. in the afternoon of Feb. 23d, 1892. He had been driving a heavy cart containing two tons of coals, when he fell off his seat, the front wheel of the cart passing slowly over his pelvis. When seen by Mr. Lane at 5 P.M. he was extremely collapsed. There was a broad, bruised line running obliquely across the symphysis, indicating the course taken by the wheel. The several portions of the pelvis moved freely upon one another. There was no tenderness or rigidity of the abdomen, and before manipulation of it without complaint. At that time his condition was not such as to encourage operation, even had there been any indication to do it. He was therefore surrounded with hot bottles and made as warm as possible. He gradually improved, and in about two or three hours after the injury began to complain of a desire to pass urine, and developed tenderness and rigidity of the abdominal wall immediately above the symphysis. On passing a catheter a little bloody urine was drawn off. By 9 P.M. the patient had recovered sufficiently to bear an operation, so Mr. Lane opened the abdomen in the middle line about the symphysis, and found some bloody urine in the peritoneal cavity. There was a large transverse rent which admitted three fingers in the upper surface of the bladder, about an inch and a half from its summit, the adjacent portion of the bladder being much bruised and swollen. The innominate bones were found separated at each synchondrosis and also at the symphysis, the fragments forming the last articulation being separated antero-posteriorly by an interval of an inch. It was apparent that the bladder had been jammed and divided by the forcible approximation of the pubic bone against the very prominent lower margin of the fifth lumbar vertebra, which, as in the case of all powerful coalheavers, was in a position of partial spondylolisthesis. The two pubic bones were placed in apposition, the rent in the bladder was closed by a continuous suture, the pelvis was sponged free of any blood and urine, and a glass tube was left in Douglas's pouch. No attempt was made to wash out the peritoneal cavity, as the urine and mucous membrane of the bladder appeared to be perfectly healthy. Subsequent to the operation but a very small quantity of bloody fluid was sucked up out of the Keith's tube, which was removed shortly. Being only too well aware how often the subjects of such severe injuries die from pneumonia, every precaution was taken to keep him in a warm, moist atmosphere; but in spite of every endeavour he developed a pleuritic rub on the left side on the day following the injury, and although his temperature on only one occasion rose to 101°, his respiration and pulse became progressively rapid, and he died on the evening of the 27th, four whole days after the injury. All abdominal pain, rigidity, and tenderness ceased, and all his urine was siphoned off through a rubber catheter tied into the bladder. At the post-mortem examination, both lungs were found in a condition of grey hepatisation, the disease being more advanced on the left side. The wound in the bladder had healed perfectly, and there was no evidence of any peritonitis.

Remarks by Mr. LANE.—Though these cases of successful suture of rupture of the portion of the bladder wall covered by peritoneum are by no means very rare, yet I think that this case, though it terminated fatally, is worth publishing. The mode of production of rupture is certainly very unusual. It serves to illustrate the fact that the peritoneal cavity is comparatively tolerant of healthy urine, and affords another example of the frequency with which a patient, the subject of a severe injury, may die of pneumonia often unaccompanied by any particular rise of temperature, although the chest itself has sustained no injury, and every precaution has been taken to shield the patient from chill. Except for the unfortunate onset of the pneumonia he might have recovered.

BEDFORD INFIRMARY.

TWO CASES OF INVERSION OF THE UTERUS.

THESE cases are examples of the common variety of inversion of the uterus (the puerperal), which is said to constitute at least 350 out of 400 recorded.[1] The diminished frequency is apparently due to the improved method of treatment in the third stage of labour; and, although there is no evidence that anything unusual was done in these cases, still it is a curious fact that a medical man was not in attendance when the birth of the children took place. For the account of the cases we are indebted to Mr. R. H. Elliot, late house surgeon.

CASE 1. (Under the care of Dr. Goldsmith.)—Emma A—— was admitted to the Bedford Infirmary on May 5th, 1891. Eight months previously to admission the patient was attended during her first confinement by a midwife, and a few days later she called in a medical man as her "womb came down." It was replaced, but she continued to lose blood, especially at her menstrual periods, when she passed clots. There was no foul discharge. On examination the abdomen was found to be rigid, and so little could be felt; the uterus was not made out. The vagina was rugose and dilatable, the cervix uteri soft and dilated; and through it presented a soft vascular tumour as large as a pear, which could be made out to be continuous all round at its base with the cervix, the finger passing into a cul-de-sac, and the sound confirmed the observation. Bimanually the uterus was not felt. There was a good deal of oozing going on, and the patient showed evidence of long-continued loss of blood in her waxy pallor and small, frequent pulse (132). She was put under ether, and Dr. Goldsmith passed a sound into the bladder, and met it above the tumour by a finger passed per rectum, thus confirming the absence of the uterus from its usual situation. He was quite unable to replace the uterus, or indeed to in any way improve its position. The patient was kept at rest, and a medicine containing dilute sulphuric acid and ergot given.

May 12th.—An injection of alum and zinc was employed to restrain the oozing, the only result being some shivering and purulent vaginal discharge on the 14th, accompanied by an evening temperature of 104·2°, which fell to 101·6° next morning. Nothing more definite appeared, and all quieted down.

25th.—Reposition was commenced with Lawson Tait's repositor, the largest cup stem being introduced.

26th.—The next-sized stem was substituted for the previous one, good progress towards reduction having been made.

June 1st.—The uterus is sufficiently reduced to allow the substitution of the smallest stem for that now in.

Later.—This had to be kept in some days to effect complete reduction, and meanwhile the cervix uteri closed upon it, making its removal very difficult and necessitating the introduction of a laminaria tent and the exercise of considerable force (under ether) before the stem could be got away. Some sapræmia ensued, but at once subsided after once washing out the uterus with carbolic lotion. The patient did well, and on July 10th the cervix still admitted the tip of the finger, and was soft. The sound passed two inches and a half. The patient was doing well, and had recovered health, colour, and spirits.

CASE 2. (Under the care of Dr. Coombes.)—Alice H—— was admitted to the Bedford Infirmary on June 29th, 1891. The patient was confined on June 8th, and was attended by a midwife, who called in a doctor, as the woman was bleeding freely. The medical man found a bleeding inverted uterus, which he replaced after removal of the placenta. The patient does not think the midwife pulled on the cord. On June 25th, as she was passing urine, the patient felt the womb come down again, causing her sharp but transient pain. She again sent for her medical man, who at once sent her to the infirmary. On admission she was anæmic, but not anxious-looking. Pulse 96; tongue moist; temperature 102°, which rapidly fell to 99°. Some retention for the first twenty-four hours had to be relieved by the catheter. Abdomen pigmented. Lineæ gravidarum well marked, abdominal walls lax. Uterus not felt, and there was no dulness over hypogastrium, but some tenderness there. On examination per vaginam a vascular tumour as big as a large orange presented. On the introduction of a duck-bill speculum the surface of the tumour was seen to be rough, especially over one part, which was evidently the placental site. Cervix uteri was soft, thin, and dilated, and embraced the neck of the tumour. Per rectum and per hypogastrium the fingers meet above the tumour. There seemed no prospect of a reduction by manipulation under an anæsthetic.

July 3rd.—Reposition was commenced with a Lawson Tait's repositor, the largest stem being used.

5th.—Half the tumour was reduced within the cervix, and the cup was accordingly withdrawn and applied to the remaining part.

6th.—The position of the cup was again changed, and it was now applied to the middle of the fundus, which alone had resisted reduction.

7th.—Stem again required readjustment.

8th.—Smallest stem substituted for the large one, the body being now within the cervix.

9th.—The smallest stem was replaced after the uterus had been douched; body reducing well.

10th.—Stem easily removed; douche given.

14th.—Involution progressing favourably; uterus still large, and cervix soft, but gaining tone. All went well, and the patient was discharged cured on Aug. 8th, 1891.

Remarks by Mr. ELLIOT.—These cases illustrate excellently the very satisfactory effect of gradually applied continuous pressure on an inverted uterus which defies all efforts at more rapid and forcible treatment. In each case the amount of pressure applied was increased (as the elastic grew slack owing to the reduction of the mass) by tightening up the perineal band. A vaginal douche was given thrice daily, and the uterus was washed out each time the stem was changed. Should any cases come under my care I would certainly alter the shape of the smallest stem by substituting a rounded convex end, with a very sloping shoulder on the stem side for the abruptly shouldered cup. I would do this for the following reasons: (1) The cup receives a portion of the fundus into it, and, a vacuum existing, one finds on attempting to withdraw the stem that one is reinverting the fundus by a sort of sucker action; (2) with a more gradual shoulder the removal of the stem would be greatly facilitated. These difficulties apply more in the cases of older standing, like the first, in which the cervix uteri returns more rapidly to its original condition of contraction.

[1] Hart and Barbour.

SOUTH DEVON AND EAST CORNWALL HOSPITAL, PLYMOUTH.

EPILEPTIFORM CONVULSIONS FOLLOWING HEAD INJURY; TREPHINING; RECOVERY.

(Under the care of Mr. WHIPPLE.)

THIS is an interesting case of epileptiform convulsions following an injury to the head. The convulsions were always general, there being no marked twitching or spasm of one set of muscles before another, but there was always marked tenderness over the scar of the scalp wound. At the operation there was no great depression of bone or collection of fluid found, but the dura mater was thickened and very adherent to the bone, not allowing the pulsation of the brain to be seen, the result, no doubt, of inflammatory thickening; there was no bulging, as if there was increased intracranial pressure, but the removal of bone must have in some way either have relieved increased intracranial pressure, or else have removed something which acted on the brain as an irritant. For the notes of the case we are indebted to Mr. R. Stanley Thomas, house surgeon.

J. T——, a seaman aged sixty-three, was admitted on December 22nd, 1891, with the following history of having in June, 1891, when at sea, fallen down the hold of the ship, cutting his head and breaking his right leg. He remained unconscious for eighteen hours; on regaining his senses, he suffered from headache for some days. Four days after the

Digitized by Google

accident he first had a fit, since then he has been subject to fits, having as many as five or six in a week.

When admitted he was a powerfully built man having on the right side of his scalp a concentric shaped scar crossing the fissure of Rolando three-quarters of an inch from the sagittal suture. Pressure over this region gave pain. No depression could be felt. He had no paralysis. His left arm he said was weak, but its power did not vary with that of the right arm any more than would naturally have been expected. His pupils were equal and reacted to light and to accommodation, no paresis of ocular muscles, optic discs normal; urine acid, sp. gr. 1018, no albumen or sugar.

From Dec. 28th to Jan. 6th he had thirteen fits, which lasted from a few seconds to a few minutes before he became conscious. During these fits he became violently convulsed at first, and unconsciousness followed for a variable period. His pulse became very feeble after a severe fit, and occasionally he would be quite collapsed. His breathing was never stertorous, but at times Cheyne-Stokes in character. He would foam at the mouth and bite his tongue, but he never passed urine or motions involuntarily. He suffered from sickness, which was always worse after the fits. He was given potassium bromide in thirty grain doses three times a day; but although the fits diminished in severity, they continued as frequently as before. As his condition had not materially improved he was given chloroform on Jan. 8th, and Mr. Whipple removed with a conical-shaped trephine a piece of bone beneath the scar the size of a shilling. The bone was very thick and the dura mater firmly adherent. No pulsation of the brain was seen, the dura being opened by a crucial incision. A grooved needle was passed in three different directions into the brain, to see if there was any collection of pus or blood, with negative result. The wound was then irrigated and sewn up with silk.

Jan. 9th.—The patient was very restless after the operation. A quarter of a grain of morphia was given hypodermically, and he slept after a second injection. He was troubled with sickness.

11th.—Still very restless. Quiet for a short time, but only after morphia. The vomiting continues. Fed by nutrient enemata and suppositories.

12th.—Head dressed. Sanious discharge under the flap.

13th.—Still very restless and strange. Vomiting continues almost incessantly. Blistered on either side of the neck over the course of the vagi.

14th.—Has passed a better night. Has kept down small quantities of milk-and-water.

17th.—Wound dressed; stitches removed. Wound quite healed. More sensible to-day than he has been since the operation. Keeping down milk. Nutrient enemata and suppositories stopped.

23rd.—Much improved. Takes solid food. Seems quite rational.

27th.—Allowed to get up.

Feb. 8th.—The patient has continued to make an uninterrupted recovery, having had no fits since the operation, and he is now able to walk about and takes his food well. To-day he is allowed to go home.

LITERARY INTELLIGENCE.—Mr. Lewis will publish immediately a Text-book of Morbid Histology, by Rubert Boyce, M.B., M.R.C.S., Assistant Professor of Pathology in University College, London, royal 8vo, with 130 coloured illustrations. The work gives a short account of the more marked histological changes in disease, designed as a practical and theoretical introduction to the higher branches of pathological morphology.

SOUTH DEVON AND EAST CORNWALL HOSPITALS.—The annual report for the past year states that the long-felt necessity for enlarging the Nurses' Institution had been accomplished and the additional rooms provided. The staff of private nurses still numbers twenty-two. It may be added that donations in aid of the hospital funds, in gratitude for the nurses' attention, had been received. The statement of the finance for the year shows an excess of expenditure over available income of £508 13*s.* 6*d.*, and, with the previous year's deficit of £704 18*s.*, the debit balance had increased to £1213 11*s.* 6*d.* Legacies received during the year amounted to £2509 18*s.* 8*d.*, but which could not be applied to the discharge of current expenses.

Medical Societies.

MEDICAL SOCIETY OF LONDON.

Appliance for facilitating Performance of Mules' Operation.—Subclavicular Dislocation of Shoulder.—Congenital Umbilical Fæcal Fistula.—Facial Chancre.—Amputation of Penis by Thiersch's Method.—Trophic Lesion following Influenza.—Syphilitic Dactylitis.—Disseminated Lupus Erythematosus.—Inguinal Colotomy.—Tumour of Humerus.—Intestinal Concretion in Lamb.—Infective Melanotic Pigmentation.

A CLINICAL MEETING of this Society took place on April 11th, the President, Mr. Jonathan Hutchinson, in the chair.

Mr. BRUDENELL CARTER exhibited an Appliance for facilitating the Performance of Mules' Operation. This consisted of a small hollow ball of indiarubber, furnished with a stopcock connected by a short tube with a detachable syringe, and capable of being quickly distended by air. As soon as the contents of the sclera were completely removed the ball was inserted, and was sufficiently filled with air accurately to occupy the cavity. The pressure thus exerted speedily arrested bleeding from the divided vessels; and as soon as this was done the ball was suffered to collapse by opening the stopcock, and was removed to make way for the glass globe, the insertion of which completed the operation. Before contriving the indiarubber ball, Mr. Carter was accustomed to fill the scleral cavity with pieces of sponge, which were tedious to insert and to remove, and which were far less efficient as a means of arresting bleeding by compression.

Mr. HUGH SMITH showed a specimen of Unreduced Subclavicular Dislocation of the Humerus. It was obtained from a widow aged sixty-nine, who about the end of October, 1889, fell down, injuring her right arm, after which she never regained the full use of the limb. At the end of April, 1890, she was found to be the subject of dislocation of the right humerus, but no attempt was then made to reduce the displacement. On June 6th, 1890, she was admitted to the Royal Free Hospital under the care of Mr. Boyce Barrow; but, in consequence of her age and the fact that she possessed good movement of the arm, no operation was performed, and she was discharged on the 19th. She died on Nov. 7th, 1891, and two days later the parts implicated in the injury were removed. Mr. J. H. Targett dissected the specimen, and found that the humerus was dislocated and rotated inwards, so that its head was resting upon the anterior surface of the neck of the scapula. The infra-spinatus and supra-spinatus muscles crossed the glenoid cavity and were inserted into a flat piece of bone which was closely connected with the greater tuberosity of the humerus. The long head of biceps was unruptured. It passed up the bicipital groove, and turned backwards at the level of the anatomical neck to reach the apex of the glenoid fossa. The latter was apparently unaltered, and the head of the bone was enclosed in a capsule formed by the anterior portion of the true capsule and the expanded tendon of the subscapularis.—Mr. SHEILD referred to the ease with which accidents of this kind might be overlooked. Three months ago a patient came to Charing-cross Hospital complaining of a sprained arm, and stating that there was no pain in the shoulder-joint. He requested the man to strip, though there appeared no reason for it, and then a dislocation of the shoulder was discovered.

Mr. WATSON CHEYNE brought a male child aged three months, suffering from Congenital Umbilical Fæcal Fistula. It appeared to be an instance in which the bowel ended at the umbilicus. An anus was present and a catheter passed up it an inch and a half. A catheter passed in at the umbilicus only appeared to take an upward direction. He imagined that it was an instance of persistent pervious Meckel's diverticulum, and he thought that though an operation to connect the gut with the rectum was feasible, yet the child would not be strong enough to survive it.

Mr. HARRISON CRIPPS exhibited a case of Facial Chancre. The patient, a middle-aged man, presented himself at the St. Bartholomew's skin department for a growth between the lip and chin. The size at that time was that of a florin.

Digitized by Google

The growth was raised a sixth of an inch above the skin level, the edges being abrupt; its surface consisted of hundreds of papillæ about the eighth of an inch in length, looking like a warty epithelioma. The surface was dry and not excoriated. There was no discharge. The history given by the patient was that he was perfectly well ten weeks ago; he was then cut by the barber whilst being shaved. Between two and three weeks later he noticed the growth first make its appearance; in about three weeks it had attained its present size. A fortnight later a rash appeared on his body, with sore-throat. The patient was now covered with a most typical secondary squamous rash. The interest in the case was the singular appearance of the primary sore, which had no resemblance to the ordinary Hunterian chancre, looking much more like an epithelioma or warty growth. Had it not been for the history of the case and the secondary squamous rash the diagnosis would have been very difficult.—Mr. HUTCHINSON had never seen a case in which the primary sore exhibited such characters, but perhaps the hypertrophy of the papillæ was due to the poulticing which the sore had undergone. He had seen in the secondary stage of syphilis a definite papillary growth at the centre of the back part of the tongue. The case was of much interest in connexion with the disease framboesia or "yaws," which observed most of the laws of syphilis, having the same incubatory period, and exhibited primary and secondary phenomena, the primary lesion being usually a papilloma and the secondary lesions large papillomatous growths. It had been described as a "syphiloid," though not true syphilis, and was said to be peculiar to the black races. He himself was of opinion that "yaws" was nothing but a papillary form of syphilis, and the case shown he held to bear out that view.

Mr. CRIPPS next showed a case of Amputation of the entire Penis by Thiersch's method. The patient, a man of forty, had cancerous ulceration of the penis, engrafted upon the scar of an old syphilitic ulcer. The disease, of eight months' duration, had destroyed the organ down to the level of the scrotum, the base of the penis being represented by a hard fungoid mass. A semicircular incision was made round this, and carried through the raphé of the scrotum, dividing it into two halves. The corpora cavernosa were dissected off the pubic bone, and cut completely away. The urethra was dissected downwards for an inch and a half, and brought out through a buttonhole slit made on the lower part of the perineum an inch in front of the anus. It was then cut off level with the skin, slit open for a short distance, and stitched to the skin. The patient made a rapid recovery, and when shown to the Society the urethral opening, which would admit a full-sized catheter, could be seen a little in front of the anus. He had perfect control over the urine, and could urinate either in the sitting or standing position with freedom and comfort. Mr. Cripps alluded to the papers of Mr. Wheelhouse, Sir W. MacCormac, and Mr Pearce Gould on this operation, and considered that there was much advantage in bringing the urethra out so near the anus, for it prevented the patient wetting himself on going to the closet.—Mr. SWINFORD EDWARDS, in a case of malignant disease of the penis, had operated by Pearce Gould's modification of this method, and on removal of the organ he found a secondary deposit at the back part of each corpus cavernosum at the point where they joined, and this had not been discovered during life, and of course would have been left behind if the organ had been ablated by the old method. Three months later the man was in good health.

Mr. SHEILD showed for Dr. MITCHELL BRUCE a case of Peripheral Neuritis following influenza. The girl suffered from this epidemic in January, 1890, and the following July complained of severe pain in the right axillary region accompanied by hyperæsthesia of the nerves of the arm and spinal tenderness. In July, 1891, there was pain in the right arm and thumb; the nail of the latter having become thick and hypertrophied, and it was evulsed without effect. At the present time there was a good deal of pain in the upper limb and in the thumb and second and third fingers. There was marked muscular weakness of the thumb but no anæsthesia. The radial and musculo-spiral nerves were tender, there was tenderness in the right axilla and over the clavicle, and there were tender spots at the tip of the thumb and over the metacarpal joints of the second and third fingers. The electrical reactions were normal.

Dr. COLCOTT FOX showed an infant aged five months, with Symmetrical Enlargement of the Metacarpal Bones of the Thumbs and of the Metatarsal Bones of the Great Toes. The child, a first one, and reputed a seven months one, had been under mercurial treatment for some weeks for a widespread syphilide, and "pseudo paralysis" of the legs and left arm. Dr. Fox said thickening of the long bones, and Wegner's osteo-chondritis with pseudo-paralysis were frequently met with. The enlargement of the hand and foot bones was much less frequent, especially of the phalanges. He had elsewhere, however, described two cases of syphilitic dactylitis in infants. The diagnosis from tuberculosis was sometimes difficult. The enlargement in this case was probably due to an osteo-myelitis.—The PRESIDENT agreed as to the rarity of dactylitis at this age, but he saw no evidence of its being an osteo-myelitis; it was probably a gummatous periostitis.

Dr. FOX likewise introduced a woman, aged thirty-one, with Lupus Erythematosus of the face, ears, and scalp, and also discs disseminated thickly over the trunk and upper arms. She had hip disease at three years old; the lupus began on the face at about seventeen years, and the trunk had been affected for about six months. The patient's father died of phthisis, and her child had suppurating neck glands. Dr Fox pointed out the rarity of these disseminated cases, and their interest from a diagnostic and etiological point of view. Kaposi, Boeck, and Hallopeau had described malignant or febrile exanthematic cases. No such attack had so far been observed in the case shown.—The PRESIDENT referred to a somewhat similar case shown at Birmingham three years ago. He had never seen a case in which the lesions were multiple and discrete, as in the present instance.

Mr. HARRISON CRIPPS exhibited a patient in whom Inguinal Colotomy had been performed nearly a year and a half ago for rectal cancer. The patient had markedly gained weight and strength since the operation, and was able to go through his daily avocations without discomfort or trouble. As a rule the bowels acted once a day.

Mr. SHEILD showed a case of Tumour of the Head of the Humerus, which occurred in a girl who had suffered from obscure pains in the right shoulder for six years. The swelling appeared to be an osteoma, and caused some displacement of the head of the bone.

The PRESIDENT showed a mass three inches long formed of fragments of undigested food, which had acted as a plug to block the duodenum of a lamb between two and three months of age, which, owing to the death of its mother, had suddenly been thrown on its own resources to obtain food, and had chosen its diet injudiciously.—Mr. SHEILD referred to the frequency with which hair-balls were found in the intestines of horses, cattle, and dogs, the nucleus being often a piece of bone.

The PRESIDENT also showed the picture of a case of Infective or Melanotic Freckles in Senility. It began with freckling, often symmetrical, of the eyelids, and then on one side the pigmentation spread. The mucous membrane and cornea were also affected, which made the case unique. He feared it might end in malignancy, for he had twice seen epithelioma develop in connexion with similar cases.—Dr. SYMES THOMPSON referred to a paper by the President some years ago on Xanthelasma and its connexion with Disease of the Liver, and he asked whether any similar connexion with internal disease was suspected in the present instance.—The PRESIDENT replied that the disease was a local one, was not symmetrical, and probably did not depend on constitutional cause.

CLINICAL SOCIETY OF LONDON.

New Method of Nephrorhaphy.—Traumatic Cyst of Pancreas treated by Incision and Suture to the Abdominal Wall.—Hydatid of Lung treated by Aspiration.—Abdominal Section followed by Parotitis.

AN ordinary meeting of this Society was held on April 8th, Sir Dyce Duckworth, President, in the chair.

Dr. WASHBOURN and Mr. ARBUTHNOT LANE read a communication on a case of Floating Kidney which was treated by a new mode of nephrorhaphy. The patient was a woman aged forty-four, and the case was one of much obscurity owing to the great mobility of the tumour &c. Mr. Lane performed an operation which he hoped would prove more permanent in its results than the method

CLINICAL SOCIETY OF LONDON

New Method of Nephrorhaphy.—Traumatic Cyst of Pancreas treated by Incision and Suture to the Abdominal Wall.—Hydatid of Lung treated by Aspiration. Mitral Stenosis followed by Paroxysmal Tachycardia.

AN ordinary meeting of this Society was held on the
Sir Dyce Duckworth, President, in the chair.

Dr. WASHBOURN and Mr. ARBUTHNOT LANE
communication on a case of Floating Kidney
treated by a new mode of nephrorhaphy. The
a woman aged forty-four, and the case was
obscurity owing to the great mobility of the
performed an operation which in its results has

usually adopted. He exposed fully the posterior aspect of the kidney and split the capsule into ten triangles by means of incisions radiating from its centre, so that when each triangle was separated from the posterior surface of the organ its base corresponded to the margin of the kidney to which it was attached. Then he carefully removed every particle of fat, transversalis fascia, &c., and after twisting each triangular portion of capsule a twisted silk ligature was attached to it. These ligatures were passed through the cut surface of the abdominal muscles, and were arranged in such a way that the posterior surface of the kidney freed of its capsule was retained immovable in immediate contact with the recently cut surface of muscle by means of its capsule, which was anchored firmly by its ten attachments. The woman gained weight and strength rapidly after the operation, and led an active life for about a year without experiencing the slightest discomfort. During this time she followed out the instructions given her—namely, that she was to avoid lifting any heavy weight, though she was encouraged to lead an active, vigorous life. In a moment of forgetfulness she attempted to move a heavy box, and at once experienced great pain in her side. This subsided rapidly, but left her with some of her original discomfort; but though the lower end of the kidney could be felt on deep palpation, there was no evidence of any abnormal mobility of the organ. As she dreaded the further development of her pain, the kidney was again exposed in the loin, when it was found to be embedded in a dense fibrous material which connected it intimately to the cicatrix in the abdominal wall. No light was thrown upon the cause of the slight return of her symptoms. The history of the case indicated the great importance of abstaining from lifting anything heavy after any operation of nephrorhaphy, however perfect.—Mr. GOLDING BIRD said that the author considered his operation better than the ordinary procedure for movable kidney, but he had not given the evidence upon which that opinion was founded; indeed, the case that he had related seemed to be an argument in the opposite direction. After operating in the ordinary way he himself had not found any return of pain, nor had the kidney left its attachment, though the patients were not limited as to exercise. He quoted several cases to show that the treatment had been very successful in his hands.—Mr. HULKE asked if other measures had been tried before resorting to suture. In several cases after operation the old symptoms returned, and the kidney became as movable as before. In many instances he had obtained excellent results by fitting the patients with a truss to which was fixed a horseshoe pad. If such an appliance was successful there was no need for submitting the patient to an operation which was not without risk.—Mr. PEARCE GOULD inquired what was meant by the "ordinary" operation of nephrorhaphy. It had at first been done by a temporary suture, which was passed through from the kidney to the skin and removed at the end of four, six, or more days. A frequent result was that the kidney became loose again afterwards; but if two permanent buried sutures were passed so as to fasten the capsule of the kidney to the posterior part of the aponeurosis of the transversalis muscle, a quite satisfactory result could be obtained. In some cases certainly the horseshoe pad had not given gratifying results. He did not see how such an apparatus could be successfully applied to control the kidney, which lay at the back of the abdomen. When a powerful muscular effort was made, any such pad must at times be quite inefficient in keeping the organ in place.—Mr. GOLDING BIRD added that when he spoke of nephrorhaphy he only referred to the modern method by buried suture.—Mr. HERBERT ALLINGHAM said that in his position as an official of the Surgical Aid Society he had seen a very large number of patients who had been submitted to nephrorhaphy, and who had not benefited in the slightest degree from the operation, the kidney being still freely movable. Under these circumstances, any improvement in the present method of operating would be a boon.—Mr. BOWLBY had seen a great many cases in which the kidney had broken loose from its anchorage. In one case operated on fifteen months ago by a surgeon experienced in these cases three buried sutures were used, and yet the kidney was quite loose and was giving as much trouble as before.—The PRESIDENT thought it was time an expression of opinion from physicians should be forthcoming. When he met with a floating kidney it was not his habit to call in surgical aid. He had known of people who had floating kidneys for twenty years, and yet remained in excellent health. Some suffered slight pelvic pain or a little discomfort at the menstrual nisus, and he held that it was not legitimate practice to interfere with a movable kidney if it gave rise to no more trouble than this. Surgeons did not seem at all agreed as to what should be done; and, if in the small minority of cases operation were necessary, there ought at least to be something like unanimity with regard to the procedure to be adopted.—Mr. R. W. PARKER referred to a patient, by occupation a cook, with floating kidney, who suffered so much pain as to be quite incapacitated from her duties. After failure of rest and pressure he cut down and stitched the organ to her side. Although it still remained quite fixed, the patient was not in the least degree relieved.—Dr. BARLOW, though he had seen a great many cases of floating kidney, had never met with one in which surgical interference was justifiable. They were met with in people prone to abdominal pain, and were much commoner among the better than among the humbler classes of society. It was a serious abdominal operation, not unattended with risks, and the physician who recommended it incurred considerable responsibility.—Mr. LANE, in reply, while he congratulated Mr. Golding Bird on the success of his cases, regretted that he and many others had not been equally fortunate. These cases of course were quite on a par with gall-stones in this: that they should not be meddled with unless they gave rise to great pain. He supposed that when patients found that no relief followed medical treatment they sought surgical aid, and this perhaps explained how it was that physicians did not seem to have met with the graver cases.

Mr. LITTLEWOOD (Leeds) read the notes of a case of Traumatic Cyst of the Pancreas. The patient, a male, aged thirty, was thrown from his horse, the horse stamping on his abdomen with his hind feet. Thirteen days after this a swelling was noticed in the left upper umbilical and lower epigastric regions. The swelling was explored and a syringeful of dark blood removed. The swelling increased in size, at first slowly, and then more rapidly. The patient suffered a good deal of pain in this region. Seven days later, August 12th, the swelling was aspirated in the morning, ten ounces of fluid removed, alkaline, dark sage-green colour, sp. gr. 1015. In the afternoon the abdomen was opened in the middle line above the umbilicus. The cyst was at once seen, having displaced the stomach upwards and colon downwards; it was covered over by omentum. This was torn through, the cyst opened, and the cyst-wall stitched to the peritoneum and deeper layers of abdominal wall; forty ounces of fluid removed of the same character as that removed in the morning; cyst drained. A sinus formed, which closed at the end of two months. Analysis of the fluid collected about ten days after the operation was made by Dr. Clarkson (demonstrator of physiology in the Yorkshire College), and shown to contain the following substances: serum-albumen, salts, trypsin, amylopsin, steapsin, and milk-curdling ferment (meta casein).—The PRESIDENT asked the author to record later the after-history of the case. The pancreas usually after such a lesion became cirrhosed.

Dr. HECTOR MACKENZIE reported a case of Hydatid of the Lung, which proved fatal by rupture into a bronchus nine hours after treatment by aspiration. The patient was a man aged twenty-six, who, until within a month of presenting himself at the hospital, had experienced no recent feeling of illness. He had then seen a doctor in order to be passed for admission to a benefit society, and had been informed, to his surprise, that there was something the matter with his right lung. Shortly after this he began to suffer from cough, shortness of breath, and from pain in the lower part of the right side of the chest, to sweat at night, and to lose flesh. On examination it was found that over nearly the whole of the upper three-quarters of the right side of the chest there was dulness with almost complete absence of breath sounds, and of vocal fremitus. Above there was a resonant area just to the right of the sternum, and the extreme apex was not quite dull. At the base there was a hyper-resonant area, over which loud friction sounds were audible, and the breath sounds were weak. The heart was displaced to the left, and the liver was displaced downwards. The diagnosis rested between new growth, hydatid, and a circumscribed pleuritic effusion. New growth and a circumscribed effusion were both improbable on account of the history. The rarity of hydatid was the only point which made that view unlikely. In

Digitized by Google

order to clear up the diagnosis the aspirator was used, and a pint of typical hydatid fluid was drawn off. No more was taken because the fluid ceased running. The patient turned very faint during the operation. After the aspiration the patient was enjoined to keep still and remain at rest. He went on well, until six hours later in the evening he commenced to cough and brought up a mouthful of thin blood-stained fluid. This was followed by urgent dyspnœa, with pallor, lividity, and cold perspirations. The cough continued, but little more fluid was brought up. This critical condition continued for over two hours before the patient died, the dyspnœa taking on more of an expiratory character. At the post-mortem examination the cyst was found to be a very large one, capable of containing about fifty ounces of fluid, and apparently existed between the lobes of the lung. A large bronchus leading to the lower lobe communicated with the cavity formed by the fibrous capsule of the cyst. This bronchus lay at the back of the cyst and had been pressed upon by it, thus accounting for the weak breath sounds heard during life over the lower lobe of the right lung. There was recent pleurisy over the right lower lobe, with the formation of fibrin posteriorly. The principal interest of the case centred in the question of the advisability of aspirating or tapping hydatids of the lung. Dr. Bristowe last year reported a case which had died during aspiration, and such deaths were not infrequent. Dr. Davies Thomas's statistics showed that while the mortality of cases left alone was 54 per cent., that of cases treated by aspiration was 27 per cent, and that of cases treated by excision of rib was 16 per cent. It seemed, therefore, both on theoretical and practical grounds, that a free opening with complete emptying of the cyst gave the best chance to the patient.—The PRESIDENT said that tapping these cases seemed to be a very common mode of treatment, and it would be interesting to know in what proportion of cases it had been resorted to in Australia, and with what result.—Dr. BRISTOWE said that, if he remembered rightly, the statistics which had been quoted had been collected from all quarters of the globe and not from Australia alone, and they included also cases of living hydatid with those in which the parasite was dead and in which suppuration had taken place. Experience went to show that the danger of tapping a living hydatid was greater than similarly treating a dead and suppurating one. When his own case was tapped little or no fluid came through the tube, but subcutaneous emphysema developed, which was followed by lividity, dyspnœa, and discharge of fluid from the mouth. At the same time the area of dulness disappeared. If the hydatid were living, the lung tissue around was compressed; but it was not usually much matted or inflamed, and hence fluid, if it escaped, would easily run into the bronchial tubes. He thought that a rib ought to be resected, and a large opening made into the chest before attempting to remove the fluid. Of the cases which had been simply tapped, many died outright, and several of those who recovered were in imminent danger for some time after the operation.—Dr. MAUNSELL said that he had spent over twenty years in connexion with large hospitals in Australia and New Zealand, and during that time he had seen considerably over a hundred cases of hydatid, infesting every region of the body. In all cases of suspected hydatid of the lung a long, very fine aspirating trocar and needle should be used for confirmation of the diagnosis and gauging the exact distance from the surface of the chest to the most superficial part of the tumour. The exploring needle should be much longer, but not much larger, than an ordinary hypodermic needle. If a larger needle were used there was danger of swamping the thoracic cavity with fluid, and causing suffocation or fatal syncope. He had never known serious symptoms to follow the aspiration of a hydatid tumour in the thorax. If the hydatid were very small and situated in the substance of the lung, it might be treated by simple aspiration, the removal of a small quantity of fluid from the cyst often causing it to wither up and undergo degeneration. If the tumour were large, and especially if it contained daughter cysts, if suppuration had taken place, or if the fluid after tapping reaccumulated, it was necessary to make a deliberate incision over the most prominent and surgically convenient part of the tumour, and completely remove the hydatid with its mother cyst. If the tumour were very large it might be necessary to remove a portion of one, two, or even three ribs in order to completely evacuate the hydatid and provide for drainage. Fully fifteen cases of this kind had come under his observation or immediate care without a single fatal result from the operation. Dr. Maunsell concluded with remarks on the treatment of hydatid in the liver and in other situations.—Dr. MACKENZIE, in reply, said that he felt convinced that a fine trocar should be used, preparations being made to follow with operation at once if the tapping should confirm the presence of hydatid. He did not know if these cases were becoming commoner, but he had seen five during the last two years; of these, two had proved fatal during the aspiration or shortly afterwards; one, which was aspirated, recovered, though at the time it nearly died; one was aspirated, and then a rib was excised, with recovery; and one, which had suppurated previously to operation, died after excision of rib.

Mr. STEPHEN PAGET read notes of a case of Abdominal Section followed by Parotitis. He described the case as an example of an acute inflammation of the parotid gland, of which he had collected upwards of a hundred instances occurring after injury or disease or temporary derangement of the abdominal or pelvic organs due to reflex nervous action and not to pyæmia. The patient was a woman aged fifty-eight who had an operation for artificial anus performed on her for the relief of intestinal obstruction on Dec. 20th, the first step being to draw out and fix to the parieties a loop of intestine. The next day, as the bowels were acting well and as the abdominal distension was all gone, the gut was rashly allowed to drop back into the peritoneum. She became restless and even delirious, and appeared for two or three days to be on the point of death. On the 24th acute inflammation of the left parotid gland set in, but the next day she began to mend, and by the 28th both the parotitis and the delirium had gone. Her further recovery was uninterrupted. He remarked that the parotitis in these cases seemed to mark a crisis occurring towards the end of the illness, and being at once followed by recovery. It is not due to any blocking of the duct, the socia parotidis which lay so near the mouth being affected only once or twice in 102 cases. The true analogues of this parotitis were to be found in the salivation of some women in pregnancy and their longing for sapid foods; in the salivation that was observed in gastritis and in cancer of the rectum, and the arrest of salivary secretion which could be produced in a dog by drawing out a loop of intestine from the abdomen.

OBSTETRICAL SOCIETY OF LONDON.

Adjourned Discussion on Cæsarean Section.

A MEETING of this Society was held on April 6th, Dr. J. Watt Black, President, in the chair.

Dr. HEYWOOD SMITH said that one of the most important points to consider was the time of operation, and he had no doubt but that it was far better to wait until labour had set in before operating, as then there would be much more chance of the uterus properly contracting. Having had the opportunity of recently witnessing Dr. Duncan perform the operation, and the great difficulty in obtaining uterine contraction, that gave rise to a considerable loss of blood, the question arose, having regard to the absence of proper healing both of the abdominal wound and also that of the uterus, whether the hæmorrhage might not have been due to that cause.

Mr. BLAND SUTTON gave the details of a case in which he had successfully performed Cæsarean section. The patient, a secundipara aged twenty-six, was the subject of spondylolisthesis, with a true conjugate of less than one inch and a half. The operation was performed without withdrawing the uterus from the abdomen, very little blood was lost, and the time occupied was only thirty minutes. The child was dead. The husband's consent having been previously obtained, the patient was sterilised by tying each Fallopian tube near the uterus by a single piece of silk. Mr. Sutton did not consider it necessary to tie each tube in two places, and then divide it between the ligatures.

Dr. CHAMPNEYS said that in a subject so large he would only allude to two or three points of practical importance. The first was the danger of uterine atony; in addition to the choice of time (after the onset of labour), it was important to prevent the uterus from being chilled. The spray was

objectionable from this point of view; so was the elastic ligature round the neck of the uterus. The second point was a difficulty which arose owing to a sort of hour-glass contraction round the child's neck, making extraction difficult. In a recent case this cost the child its life although it was recognised early, and the head was promptly and powerfully pushed up by an assistant. The third point was the best way of sterilising the patient. If the tube were tied in two places and the piece cut out, it left a raw and bleeding edge of meso-salpinx. The best way was to tie the tube simply, then to pinch up a loop of tube, to tie this with the ends of the first ligature, and then to cut off the loop of tube.

Dr. DUNCAN thought that the Cæsarean section was to be preferred to Porro's operation except in cases where there were uterine tumours, which could be removed at the same time; also where the uterus was affected with cancer, as here the offensive odour and discharge were very likely to cause fatal peritonitis if the uterus was left. Hitherto he had preferred and practised bringing the uterus outside the abdomen before opening it, considering that by doing so the complete prevention of the passage of blood, amniotic fluid, or meconium into the peritoneal cavity more than counterbalanced the risk attending the longer external incision. He narrated a case, however, on which he had performed Cæsarean section since the last meeting of the Society, and which was doing well on the eighth day; but several hours after the stitches were removed, and in spite of plaster having been applied over the abdomen, the whole length of the abdominal incision was torn open during a sudden fit of coughing, the intestines protruded even down on to the thighs, and death from collapse ensued about thirty hours after. Notwithstanding Dr. Murdoch Cameron's opinion and larger experience of Cæsarean section, he preferred choosing his time for operating, and did not wait until labour had set in. He considered that placing an elastic ligature round the cervix was not good, as it tended to cause asphyxia of the child and paralysis of the uterine muscle. He also thought that hour-glass contraction of the uterus could be absolutely prevented by taking care to effect delivery of the child before rupturing the membranes.

Dr. HORROCKS thought that if Cæsarean section and Porro's operation had equal mortalities, then the former would be preferable as being less of a mutilation, but both operations were good, and should be done respectively in suitable cases. He thought Porro's operation should be selected in cases of rupture of the uterus and certain cases of tumour complicating pregnancy. Cæsarean section at the present time could not be compared with cases operated on in the past, as formerly it was done as a *dernier ressort*, and without antiseptic precautions. He had operated by Sanger's method three times and assisted at a fourth. Two of the former died; the other two and all the children recovered. He considered that removing the uterus out of the abdomen before delivery was fraught with danger, and should be avoided if possible. The elastic ligature did not, he thought, prevent uterine contraction. Sanger and Leopold had used it with impunity. In all his cases the operation was performed before labour had set in. Bringing the peritoneal surfaces together by numerous fine silk sutures, as insisted upon by Sanger, occupied much valuable time, and speed was an antiseptic. In one case he inserted a drainage-tube through the cervical canal, but it caused hæmorrhage, and was soon removed. He emphatically stated that it was not necessary for the uterus to be actively contracted in order that hæmorrhage should be stopped. All that was necessary was retraction—that is, contraction having taken place, the fibres then relax, but are not stretched out again; hence it was useless stimulating the uterus farther, unless hæmorrhage was actively taking place. He showed sections of the Fallopian tubes made seven days after they had been tied with kangaroo tendon, proving complete obliteration of the lumen of the tube.

Dr. ROUTH wished to speak on three points: 1. To operate on a woman on whom the Cæsarean section had been once performed successfully was a proceeding almost free from danger, as the adhesions contracted between the womb and abdominal wall converted the operation into an extra-peritoneal one. From the tenour of the discussion he believed Cæsarean section would in future be much more frequently performed; and the improvements in abdominal surgery justified one in believing the results would be much more favourable. 2. In the case of a first operation it was very important to ascertain if the child were alive or dead, especially if it had been long dead, as it might be putrid; and in these cases, even with every aseptic precaution, it was very difficult to prevent poisoning. Dr. Duncan had mentioned such a fatal case in cancer of the cervix, and he (Dr. Routh) had had a case in which child and membranes were putrid, and which ended fatally. In these cases Porro's operation was preferable, and safer than Cæsarean section. 3. The incision into the uterus should be made at its upper two-thirds, carefully avoiding the cervical portion, as, if this were incised, the uterine contractions would tend to open the cut cervical portion and make a strain on the ligatures.

Dr. BRAXTON HICKS said that formerly it was a question whether any stitches should be put into the uterine wound or not, and many cases recovered that were not sewn up. He considered the recent improvement in the death-rate was largely owing to the increase in the number of stitches used. He expressed his consent to the advantages of Porro's operation in cases of uterine fibroids, and mentioned a case of the kind under his own care in which a large sinus running across the incision was divided; the bleeding could not be restrained except by undermining.

Dr. HANDFIELD JONES also made some remarks.

Dr. LEITH NAPIER, in reply, said that up to March 23rd Leopold had performed Cæsarean section forty-six times and Porro's operation four times. Of these, forty-six mothers and all the children were saved. Dr. Murdoch Cameron's total now reached eighteen, with two deaths; so that the maternal mortality of these two operators was under 9 per cent. Turning the uterus out of the abdomen before opening it was in some cases unnecessary; in others it greatly simplified and expedited the operation. On the whole, he thought it better to remove the child before extruding the uterus. As to the elastic ligature, although probably the dangers of asphyxia of the child and post-partum uterine atony were exaggerated, he thought it wise, unless reliable assistance were obtainable, to continue using it. With regard to the question of operating before or after labour had set in, there were *pros* and *cons* either way. Harris's cases of uterine tolerance after injury showed that it was not essential to wait for labour pains. He was glad to find Dr. Champneys now adopted the suggestion of cutting the tubes across rather than simply ligaturing them. Dr. Duncan had anticipated his reply to Dr. Champneys' hypothesis that the severed ends might bleed. As a matter of observation there was no oozing, and the divided mucous membrane became retracted within its peritoneal covering; the doubling up was unnecessary.

Dr. JOHN SHAW having made a few remarks, Dr. CULLINGWORTH said, in reply, that, with regard to waiting in all cases until labour had commenced, he did not agree with Dr. Cameron that this was necessary. The advantages of operating in the daytime were obvious, and experience showed that the operation itself was sufficient to excite uterine action and ensure full contraction. He much preferred opening the uterus and removing its contents *in situ*, as it obviated the necessity of a long abdominal incision and possible exposure and chilling of intestines. The uterus, after being emptied, could be brought out if thought desirable, in order to facilitate the suturing of the uterine wound. He regarded as distinct improvements the abandonment of the elastic ligature and the arrest of hæmorrhage from divided sinuses by direct pressure on the cut surfaces. Another advance was the method of suturing by a moderate number of deep and half-deep sutures, doing away with the wearisome peritoneal suturing, until recently thought to be so essential. He recommended those interested in the subject to read a very useful little paper by Dr. Kelly, published in the *American Journal of Obstetrics* for May, 1891, entitled "The Steps of the Cæsarean Section—the Do's and the Dont's." He regarded Porro's operation as a most valuable resource in exceptional cases, and thought that increased experience would enable us to formulate the conditions in which the one or the other operation was to be preferred.

The following specimens were shown:—

Dr. LEITH NAPIER: Axial Rotation of Parovarian Cyst.

Dr. WILLIAM DUNCAN: Uterus, Kidneys, and Ureters from a case of Cæsarean section.

Dr. GILES: (*a*) Congenital Diaphragmatic Hernia; (*b*) Malformed Fœtus (with a drawing).

Dr. CULLINGWORTH: (*a*) Ruptured Tubal Gestation; (*b*) Uterus extirpated for Squamous-celled Carcinoma, which had spread upwards instead of downwards.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.

The Customs and Inland Revenue Act.—Interpretation of Terms in Sanitary Acts.

A MEETING of this Society was held on March 21st, when Mr. S. F. MURPHY, President, occupied the chair.

Dr. SYKES read a communication on the difficulties attending the working of Section 26, Sub-section 2, of the Customs and Inland Revenue Act, 1890, under which houses originally built or adapted by alterations, and used solely for providing separate dwellings for the working classes at rents not exceeding 7*s.* 6*d.* a week, might be exempted from inhabited house duty if certified by the medical officer of health to be so constructed as to afford proper accommodation for each of the families and persons inhabiting them, with due provision for their sanitary requirements. No definition of these conditions was given, and the Local Government Board and the Commissioners of Taxes declined alike to afford assistance or information. The Commissioners and the local authorities too differed in their definitions of "separate dwellings." Dwellings might be wholly or partially separate according as they possessed separate or common entrances, and as the sanitary conveniences were used in common or each "dwelling"—i.e., suite of rooms—had its own. The degradation of adapted or "made down" houses was largely due to the absence of proper control of the common stairs, and it would be a matter for grave regret if block dwellings deteriorated from this cause. The Commissioners maintained that gates closed at night to all but the tenants made the building a single house, for which exemption could not be claimed; but some such control was necessary to prevent the common stairs from being the resort at night of "dossers," vagabonds, and prostitutes; but if the block were deemed to be a private house and the stairs not a part of the public street, police supervision could not be obtained. He moved: "That the Society of Medical Officers of Health considers as unsatisfactory the absence of control over the common stairs of houses let in lodgings and block dwellings in large towns."—The resolution was seconded by Dr. Parkes, and carried unanimously.

Dr. WILLOUGHBY then read a paper on the Conditions constituting (1) an Unhealthy Area, (2) a House unfit for Human Habitation, (3) and Unhealthy or Insanitary Houses; or the circumstances under which the (1) Housing of the Working Classes Act, Part I., or (2) Part II., or (3) the Public Health Acts respectively, should be applied. His intention was, he said, rather to elicit than to impart information, to ascertain the views and practice of others, and thus to arrive at a clear conception of what was to be understood by each of these expressions, and agreement as to the best line of action in dealing with the several classes of insanitary property. He would define an unhealthy area "as one in which (1) the majority of the houses were unfit for human habitation, or (2) were so arranged that reasonable ventilation was impossible, or (3) were incurably damp, or (4) the ground beneath which was saturated with sewage." Among irremediable defects rendering a house unfit for human habitation without entire reconstruction were: (1) "rotten and mouldy" houses, in which the damp was most evident near the ground and on the party walls, not being caused by defective roofs or gutters, and frequently haunted by diphtheria; (2) houses in blind or labyrinthine alleys, back-to-back houses without forecourts or overshadowed by lofty buildings (though there were back-to-back houses which he could not conscientiously condemn); and (3) houses with old and defective brick drains, the ground beneath which was saturated with the sewage of successive generations, generally to be recognised by the presence of rat holes in the floors and walls. Houses unfit for human habitation to be dealt with under the Housing of the Working Classes Act, Part II., if in groups, or the Public Health Act if single, were those in which (1) the conditions just described existed, (2) houses so dilapidated as to be past repair, and (3) in which the structural defects as regards the admission of light and air, drainage of the basement, the position of the waterclosets, &c., were such that their removal, though physically possible, would involve a prohibitory expense. The ideal plan of house drainage, which he always required in certifying houses of the better class, with disconnexion of the soil-pipe, a separate ventilating pipe at the head of the drain, and inspection chambers at either end, was out of the question in those occupied by the great majority of the middle and lower classes; but practical security against the entrance of sewer air might be obtained by using the soil-pipe as the upcast ventilator, and interposing between the house system and the sewer a small stoneware interceptor, with a syphon beyond it. The great difficulty in the case of small houses without areas or forecourts was to find a place for even the smallest interceptor, while without a manhole exploration of the drain involved breaking up the ground. He showed plans of an arrangement by which complete interception, ventilation, and facilities for exploration and flushing could be secured for an entire block or street section of a score of houses at the minimum cost, while all drains beneath the houses would be avoided. He would carry a common drain in the rear of each section from the footway of one cross street to that of the next, into the sewer of which it would discharge. There would be a manhole in the footway at each end, with provision for ventilation &c., as in houses of the highest class, save that, access being from the street, it would be under the control of the sanitary authority. Into this would be led from the houses on one or both sides the separate drains, ventilated by their soil pipes and uninterrupted by syphons &c. Again, considering the utter hopelessness of keeping a multitude of private cisterns covered and clean, he would propose that all the houses in a section of a street be supplied through pipes from a large common concreted cistern, erected somewhere in the rear, in a brick chamber, accessible only through a door, the keys of which should be kept by the sanitary inspector and the turncock.—Drs. TATHAM (Manchester) and SYKES (St. Pancras) severely criticised the provisions of the Housing of the Working Classes Act, especially as to appeals, arbitration, and compensation.—Dr. KEMPSTER stated that an arrangement for the combined drainage of rows of houses, with automatic flushing almost identical with Dr. Willoughby's, and controlled by the sanitary authority, had been carried out on the Shaftesbury-park estate.—Dr. WILLOUGHBY then briefly replied.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

A MEETING of the Surgical Section was held on March 4th, Mr. Croly, President, in the chair.

The Treatment and Origin of Hammer-toe.—Mr. SWAN read a paper on the treatment and origin of Hammer-toe, and demonstrated that the skeleton was at fault. He deprecated the treatment usually recommended, of division of certain of the soft tissues. From a number of facts which he stated as to the functions of the toes in certain races and the functional adaptability of the second toe, and from a comparison of the feet of anthropoid apes with the lower and higher types of the human foot, and from a review of the embryological development of the human foot, he refers the distortions of equino-varus and other congenital aberrations from the higher type—hammer-toe included—to either an arrest of the evolutionary process, or to a reversion to a lower type, with an unequal development of the osseous and soft tissues.—Mr. HAMILTON considered the Academy was indebted to Mr. Swan for his paper, which was characterised by originality and research, as well as by practical usefulness. The surgeon was apt to follow routine, and he had himself on many occasions divided the flexor tendons for this affection. He had no doubt, from what he now saw, such teaching was erroneous. He had himself been struck with the functional usefulness acquired by the toes, as illustrated by the divers in the Bay of Naples.—Mr. T. MYLES disagreed with some of Mr. Swan's statements, and considered that his deductions were hardly warranted in their entirety. For instance, the second toe, normally, was not shorter, but always longer than the first. Mr. Myles pointed out that in the condition under discussion the position of flexion of the second toe had the effect of removing the broad anterior extremity of the phalanx from between the first and third, and was, in fact, nothing more than a spontaneous effort to diminish the effects of the crowding together of the toes by tight boots.

Some Remarks on Excision of the Elbow joint.—The PRESIDENT (Mr. Croly) made a communication on resection of the elbow. He first described cases suitable for excision, and said the last thing that entered his mind in elbow-joint disease was amputation. Fortunately in disease of

Digitized by Google

the head of the drain, and inspection chamber end, was out of the question in those occupied by the majority of the middle and lower classes; but security against the entrance of sewer air might be by using the soil-pipe as the upcast ventilating pipe between the house system and the sewer, or else an interceptor, with a syphon beyond it. The difficulty in the case of small houses without mews courts was to find a place for even the smallest manhole while without a manhole exploration of the drains meant breaking up the ground. He showed plans of an arrangement by which complete interception, with facilities for exploration and flushing could be made for an entire block or street section of a sewer at a minimum cost, while all drains beneath the house could be avoided. He would carry a common drain out of each section from the footway of one row of houses to the next, into the sewer of which it would form the There would be a manhole in the footway at each provision for ventilation &c., as in houses of the class, save that, access being from the street, it would be under the control of the sanitary authority. It would be led from the houses on one or both sides by rain drains, ventilated by their soil pipes and sewers by syphons &c. Again, considering the cost and difficulty of keeping a multitude of private cisterns efficient, he would propose that all the houses in a certain area should be supplied through pipes from a large common cistern, erected somewhere in the rear, in a yard accessible only through a door, the keys of which were kept by the sanitary inspector and the tenants. TATHAM (Manchester) and STEER criticised the provisions of the Housing of the Working Classes Act, especially as to appeals, and urged cooperation.—Dr. KENNETT stated that an arrangement for the separate drainage of rows of houses with trapped drainage almost identical with Dr. WILLOUGHBY's had been carried out by the sanitary authority, had been successful on the Shaftesbury-park estate.—Dr. WILLOUGHBY replied.

ROYAL ACADEMY OF MEDICINE IN IRELAND

A MEETING of the Surgical Section was held on the 4th inst. Mr. O'Kelly, President, in the chair.

The Treatment and Origin of Hammer-toe, and demonstrated that the skeleton was that of a monkey. He deprecated the treatment usually recommended, dividing certain of the soft tissues. From a similar consideration of the functions of the toes in man, which he stated as to the functional adaptability of the second toe, and the functional adaptability of the second toe in a comparison of the feet of anthropoid apes with those of higher types of the human foot, and from a review of embryological development of the human foot, he traced portions of equino varus and other congenital deformities from the higher type—hammer-toe included—to an arrest of the evolutionary process, or to a reversion to a lower type, with an unequal development of the muscles and soft tissues.—Mr. HAMILTON considered the Academy indebted to Mr. Swan for his paper, which was remarkable by originality and research, as well as by practical importance. The surgeon was apt to follow routine, and had himself on many occasions divided the flexor tendons in this affection. He had no doubt, from what he had seen, such teaching was erroneous. He had himself been taught with the functional usefulness acquired by the toes, illustrated by the divers in the Bay of Naples. Mr. MYLES disagreed with some of Mr. Swan's statements. He considered that his deductions were hardly warranted in their entirety. For instance, the second toe, he thought, was not shorter, but always longer than the first. He pointed out that in the condition under discussion the flexion of the second toe had the effect of shortening the broad anterior extremity of the phalanx between the first and third, and was, in fact, nothing more than a spontaneous effort to diminish the effects of the deformity together of the toes by tight boots.

Some Remarks on Excision of the Elbow-joint.—Dr. KIDENT (Mr. Croly) made a communication on this subject. He first described cases suitable for the operation, the elbow. He then described the method of operating, and said the last thing that entered his mind was amputation. Fortunately the disease was

the elbow the humerus was more extensively diseased than the bones of the forearm. He preferred the single incision, made about five inches long, the arm being held as straight as possible during the operation. The ulnar nerve, in diseased joints, in his experience is not necessarily seen. He laid particular stress on the importance of removing a portion of the shaft of the humerus in addition to the condyle, otherwise a stiff joint would be sure to follow. He exhibited a number of specimens of his cases from the museum of the College, showing the amount of bone removed. He also exhibited a radius and ulna from the bone-room of the College, showing the insertions of the biceps and brachialis anticus, the latter insertion being sufficiently low to allow of the removal of the coronoid process. He laid stress on the importance of early passive movements. If sufficient bone were removed no fear of ankylosis need be entertained.—Mr. WHEELER said that he had also cases in which there were scarcely any symptoms to warrant operation as far as regarded external appearances. Some of these cases he described under the head of silent caries.—Mr. BARTON said that in his experience excision had rarely to be performed for ankylosis in flexed position. He endorsed what the President had stated as to the time required for a useful cure, and believed twelve months necessary.

Reviews and Notices of Books.

Consumption: How to Prevent it and How to Live with it. By N. S. DAVIS, jun., A.M., M.D. Philadelphia and London: F. A. Davis.

THIS volume is intended partly as a manual for phthisical patients, giving them the hygienic rules &c. by which they must live, partly as a popular exposition of the nature and causes of "consumption," with the view of interesting the public in its preventive treatment. The author believes that the disease "could be reduced everywhere to very moderate limits if the bodies of children and growing youths were properly developed physically, and if the hygiene of our homes, our offices, and our factories was more perfect than it is." With the view of making the volume of value to medical practitioners, information on climate, exercise, &c., is added. On the whole, the author has executed his task very fairly, though the limits he has imposed upon himself render his work only a slight sketch of a large subject. He does not regard phthisis as contagious, and refers to the futile attempts which were made to stamp out the disease in Portugal and in Naples by vigorous methods of rigid isolation. He agrees with most authorities in regarding the sputa as the main source of its dissemination. He puts climate in the front rank as a curative agent. "The ideal home for the consumptive," he says, "must be where the air is exhilarating, dry, clear, and pure. For those who are greatly enfeebled the location must be one that is free from frequent high winds or intense cold. Coldness is rather beneficial than otherwise to those predisposed to the disease, or who are still fairly vigorous. A rarefied air is also a benefit to them. The ideal home must be so located as to afford its inhabitants tempting and attractive occupations. Whether this locality should be an elevated one with a thin and dry air, or at the ocean-beach with a heavier and moister air, will depend upon the nature and degree of change in the lungs of the individual." Much valuable and not too hackneyed information is given regarding the health resorts of Colorado, Texas, Arizona, Florida, California, &c. On the question of diet, Dr. Davis lays down many good rules. Among others, he says: "For those who have little or no daily fever, an abundance of sugars, starches, and oils are the best; but if fever is quite constant and high, a larger proportion of albumen usually proves most serviceable." The author deprecates the use of alcohol in consumption, remarking that "alcoholics continuously given only heighten the deleterious effect of the disease. Not only is tissue-change, which involves the natural elimination of used-up matter, interfered with, but the capability of the tissues to take up new matter is also lessened." He states that "statistics have been gathered which show that those consumptives who use liquors live, on an average, some months less than those who do not." We should be glad to have the statistics, as the point at issue is one of great importance. On the whole we can commend this little work. Its perusal will help any intelligent reader to a true understanding of the nature of consumption, and of the modes in which the lay public may best coöperate with medical men in arresting the greatest scourge of our civilisation.

The Practitioner's Handbook of Diseases of the Ear. By H. MACNAUGHTON JONES, M.D., and W. R. H. STEWART, F.R.C.S. Ed. Fourth Edition. London: Baillière, Tindall, and Cox. 1892.

THE fact that a fourth edition of this work is forthcoming is a sufficient proof of the increasing interest that is taken by the profession generally in the subject of aural surgery. The present edition is enlarged and copiously illustrated.

On examining this work with scrupulous care, we must confess to a feeling of disappointment. In the classification of subjects, the etiology of diseases, and especially in composition, evidences could be quoted of undue haste and want of consideration. Many sentences might be instanced which are so long and involved that the authors' meaning would be ambiguous to all but those previously well versed in the subject. In the classification of etiology grouping from a pathological standpoint is hardly aimed at. No less than three long chapters are devoted to the consideration of tinnitus aurium and its treatment. The authors deserve credit for their attempts to throw light upon a very obscure subject. We question, however, if they have handled the matter judiciously. For instance, the ascribed and recognised causes of tinnitus, in cases where the hearing was normal, are thus stated: "Recent sea-bathing, fever, alcoholic excess, tropical causes, cardiac weakness, nasal obstruction, puerperal eclampsia, irregular catamenia, mental strain, over-study, menorrhagia, Bright's disease, the menopause, albuminuria, quinine, retroflexion of the uterus with neurosis, pharyngeal catarrh, neurotic temperament, tobacco"! The directions for treatment of a "cold in the head," on page 176, are no doubt excellent, but are as much out of place in a work on aural surgery as a detailed description of the removal of an aural polypus would be in a work on General Medicine. Though the book is enlarged after this fashion, we note that subjects of such importance as operations upon aural exostosis and the instrumental treatment of impacted foreign bodies receive but scanty notice.

The affections of the nose and naso-pharynx complicating ear diseases are fully dealt with in a separate chapter. The authors advise "massage" as of use in certain cases of nervous deafness attended by tinnitus, and in "progressive deafness" due to chronic middle ear changes. We venture to think that before recommending this treatment to students and practitioners very distinct indications should be laid down for its employment, and we must express a difficulty in understanding how "tapotement" over the mastoid could possibly benefit chronic "progressive inflammation" in the tympanic cavity.

The illustrations are very abundant, but some of them are not well executed. While giving due credit to originality and research, we question the necessity of a well-known author attaching his name to such common and trivial inventions as ear-protectors, oral protectors, hand douches, and insufflators. On the pilocarpine treatment, as might be anticipated, the authors write with authority. We notice

Digitized by Google

that they discourage the use of this drug in chronic affections of the middle ear.

The chapter on the use of electricity by Dr. Cagney is good, and affords a useful guide to those who feel disposed to advise its employment. The directions for using the tuning fork in cases of supposed nerve deafness are clear, and throughout the work portions may be selected which are worthy of praise. Again, though some of the illustrations are indifferent, the coloured plates at the commencement of the book afford excellent representations of such appearances of the tympanic membrane as perforation, chronic inflammation, and cretaceous deposit. The work would not suffer by more careful writing, a more methodical system of classification, and a revision of the illustrations. Even in its present form, however, anyone who reads it will not fail to increase his knowledge of what is taught and practised by many modern authorities in aural surgery and nasal affections.

OUR LIBRARY TABLE.

Traité Clinique et Thérapeutique de l'Hystérie. Par le Docteur GILLES DE LA TOURETTE. Paris: E. Plon, Nourrit, et Cie. 1891.—This is an exhaustive treatise which may be said to embody the views which are current at the Salpêtrière. It is the work of one of the most indefatigable of Charcot's disciples, and it has received the imprimatur of the master himself in the form of a preface. Such prefaces are unfortunately not uncommon, and in such a case as this, while a preface from one from whom may be said to have emanated most of the current doctrines with reference to hysteria as the word is understood in France would have had a certain peculiar value, it is a distinct disadvantage that it is only one among a number. Apart, however, from the preface, we have nothing but praise for the work. The subject is treated in an interesting manner, it is discussed thoroughly, and so far as possible an endeavour is made to elucidate it. The first chapter (there are twelve in all) is devoted to a historical review of the various writings which deal with this and cognate subjects; while the remaining chapters are occupied in setting out and enlarging upon the characters, symptoms, and origins of a disease as obscure as it is interesting. If we were to single out one chapter as more particularly interesting than the rest, our choice would certainly fall upon the eighth, which discusses the various hysterical, or so-called hysterical, affections of vision—a subject which is important in several aspects. But all the parts are interesting, and the book as a whole will be valuable so long as it is kept in mind that such cases as are described in it, and such clinical entities as are recognised, are only to be met with at the Salpêtrière, and so long as we remember that in that school especially there is a tendency to classify as hysterical any obscure case which recovers. We know of no work, however, which gives so graphically, so succinctly, and at the same time so completely, an account of the various vague symptoms and signs which are embodied in the somewhat shadowy figure of hysteria.

Health Springs of Germany and Austria. By F. O. BUCKLAND, B.A.Oxon., M.D. Second Edition. 1892.—Dr. Buckland only claims for his little work that it may prove useful to those who have not time for the perusal of the larger works on the same subject. It consists of a general sketch of the spas of Germany and Austria, and the information given is somewhat scanty, and has no pretence to originality. To take two typical examples. The following is the amount of information given regarding two of the most interesting and important problems connected with this subject—viz., the treatment of syphilis at Aix-la-Chapelle and the treatment of diabetes mellitus at Carlsbad. Regarding the former, the writer says: "The treatment consists in Tigismund's process of inunction, modified so as to suit the course of sulphur baths, together with an internal course of the waters." Regarding the latter, he says: "In this disease [i.e., diabetes] the amount of sugar is diminished and the symptoms generally improved. Life is undoubtedly prolonged, patients being known to return to Carlsbad for twenty years in succession. The number of visitors suffering from this malady increases annually. The effect of the waters does not manifest itself till about two months after the course, and therefore patients must not be disappointed if urgent symptoms are not relieved during the period allotted to drinking." Other leading questions of balneo-therapeutics are dismissed with equal brevity. While Dr. Buckland's book is thus a very slight sketch, only suitable for those approaching the subject for the first time, we have not noticed any important errors, and no doubt many non-professional readers will find the information given as much as they will be inclined to digest.

Indigestion, Clearly Explained, Treated, and Dieted; with Special Remarks on Gout, Rheumatism, and Obesity. By THOMAS DUTTON, M.D. London: H. Kimpton. 1892.—There are many points in connexion with the study and treatment of dyspepsia which still require elucidation, and, although the physiologist and chemist are being pressed into the service, it cannot be said that we have as yet much sound scientific knowledge upon this common condition, which embraces many varieties of functional derangement. The *brochure* by Dr. Dutton is not intended to open up new paths of inquiry. It is rather a description in simple language of the prevailing knowledge of the causes and symptoms of the chief forms of indigestion and their treatment. The author has treated his subject with discrimination, and the hints contained in the book as regards the preparation of foods and the general management of the dyspeptic may prove of service to many.

THE February and March numbers of the *Veterinarian* both contain matter of considerable interest. In the February number Mr. W. Ashton Hancock, M.R.C.V.S., contributes a paper on Tuberculosis, its Prevention and Suppression, in which he holds "that it is not a particularly difficult task to diagnose tuberculosis, especially in the lungs of the living animals, even without the history to guide you." He gives his reason for taking up this position. He also maintains that (1) periodical examination of all dairy stock by veterinary inspectors, (2) isolation and slaughter of all condemned cows, (3) compensation to the owner, and (4) the licensing of dairies would go far to help in diminishing the amount of tuberculosis in this country. In the February number there is commenced an interesting discussion on pleuro-pneumonia, a report of which is continued in the March number. There appears to be very great dissatisfaction, or at any rate disagreement, as to the course of study and method of examination necessary for the veterinary diploma. Those who are interested in the subject will find much of value in Captain Raymond's paper on General and Veterinary Education, and also in the discussion on the report of the Court of Examiners for the veterinary diploma in England and Scotland. Of course the teachers hold that the examination is at fault, and the examiners hold that the fault is in the teachers. There can be little doubt that the outcome of such a discussion will be new methods of both teaching and examination which will prove of advantage to the student.

DISEASED MEAT.—At Walsall, last week, a butcher was fined £25 and costs, or in default two months' imprisonment, for exposing for sale a quantity of meat which was unfit for human food. It was stated that the meat consisted of the carcase of a ewe sheep, which had not been slaughtered, and which defendant bought for £1, and a cow, for which he paid £1 6s.

THE LANCET.

LONDON: SATURDAY, APRIL 16, 1892.

THE Irish Local Government Bill which has lately been brought before the House of Commons by Mr. BALFOUR, and concerning the political issues of which a party battle will shortly rage, deserves some examination and attention in its sanitary aspect, as well as comparison with the sister English and Scotch Acts of 1888 and 1889 respectively, which have already received the Royal assent.

On first perusal of the Bill we must confess to some feeling of disappointment at the somewhat disjointed and fragmentary character of the sanitary provisions. But this is soon seen to be unavoidable, inasmuch as the whole kernel of the measure is the power to transfer the functions of boards of guardians, as rural sanitary authorities, to the newly formed County and Baronial Councils. And here Mr. BALFOUR may be congratulated on having succeeded in framing a combined measure of county and district government, by taking advantage of the existence of the Irish barony, and adopting the latter as his administrative unit. In this respect the Irish Bill is superior to both the English and the Scotch Acts.

Clause 10 transfers to the County Council the powers of boards of guardians relating to the execution of the Contagious Diseases (Animals) Acts, 1878–90.

Perhaps the most important sanitary clause of the Bill is Clause 12. This transfers to the County Council the powers of rural authorities relating to the Public Health (Ireland) Act of 1878, the Housing of the Working Classes Act of 1890, the Labourers' (Ireland) Acts of 1883–86, and the Factory and Workshops Act of 1891. For the purposes of this business the county is to be divided into Sanitary Districts, presided over by a Sanitary Committee, consisting of a sufficient number of County and Baronial councillors to represent the cess-payers of the district. These resemble the Districts and District Committees of the Scotch Act. The Sanitary Committees formed as above stated are to be invested with the powers of the rural authorities within their districts, except that they cannot appoint officers or raise money; and are to be entirely under the control of the County Council, which is empowered to secure proper performance of duty on the part of each Sanitary Committee. There is also a power of appeal to the County Council against the Sanitary Committee on the part of the health officer or sanitary inspector of the county. Section 6 of this clause is important, as it gives power (unfortunately, permissive) to the County Council to appoint officers under the Sanitary Acts for any part of the county, duly assigning the area. Their duties and tenure are to be the same as those of the officers of the local district. Finally, Section 10 enacts that if three-fourths of the Irish counties adopt Clause 12, the remaining fourth may, by order in Council, be obliged to do so. Clause 13 gives power to the County Council to enforce the provisions of the Rivers' Pollution Prevention Act (1876), as in the English and Scotch Acts, and to form a Joint Committee as in those Acts. Clause 21 gives power of transference to County Councils of powers of local bodies—e.g., drainage boards. Clause 36 invests the County Council with important borrowing powers for sanitary works and improvements. Clause 42 enacts that the expense of the execution of business transferred from boards of guardians is to be kept separate from the other expenses of the Council, and to be defrayed out of a sanitary rate to be fixed by order of the Local Government Board. This order is to differentiate the rate for "general" and for "special" expenses, as in the English Public Health Act of 1875 (Sec. 229). Clause 50 authorises the formation of a Standing Joint Committee of the County Council and the Baronial Council, and Clause 52 imposes the necessity of the appointment, amongst other officers, of a medical officer of health "for the Sanitary Acts by this Joint Committee." His tenure of office, however, is not so secure as that of the county surveyor, for the latter can be dismissed only "with the concurrence of the Standing Joint Committee," whereas the health officer can be removed at the pleasure of the County Council.

Such are the main sanitary provisions of the proposed Act to extend local government to Ireland. In criticising them we cannot but accord praise to the conception of establishing the superior and the subordinate (or, more accurately, coördinate) bodies at one and the same time. The appointment of a health officer by the Standing Joint Committee of the County and Baronial Councils, under Clause 52, Section 6, is a distinct advance on the provisions in the English and Scotch Acts which make the county health officer's services "available" in the district. But here praise ends. The Bill is far too permissive. The main sanitary change—that of the transference of the powers of rural authorities to the new Councils—is itself to a great extent permissive; so is the appointment of "officers under the Sanitary Acts" by the County Council; and so, too, is the formation of the Standing Joint Committee of the County and Baronies. The appointment of a health officer by the latter is the only obligatory provision of the kind. These defects should be remedied in Committee. Besides these there is a serious omission in not giving the County Council power to make by-laws, which is contained in both the sister Acts. Again, no attempt is made to attract men of special attainments to the public service, by insisting on the possession of a State medicine diploma, as is now necessary in England and Scotland; or to secure them from arbitrary dismissal at the hands of incompetent or apathetic Councils. Further, in the case of there being no joint health officer, but only a county officer, there is no power given to the County Council, on the report of their officer, to make a representation against recalcitrant Baronial Councils to the Local Government Board or the Board of Supervision, as in the English and Scotch Acts respectively.

We trust that our criticisms may bear fruit in the reconsideration by the Government of some of the more important defects and omissions in sanitary administration which we have pointed out, and that before the Bill becomes law they may be corrected in a broad spirit of true statesmanship.

LORD KNUTSFORD has kindly forwarded to us Dr. POUPINEL DE VALENCÉ'S report to the Colonial Office, in which he gives an account of his experiments made

Digitized by Google

with tuberculin on five lepers at the Barkly Asylum Public Hospital, Mauritius. Two of these cases can be excluded from consideration because they refused to go on with the treatment, although there had not been any evil effects. There remain therefore only three in which it was thoroughly tried. The treatment for all of them was simultaneously commenced at the beginning of May, 1891. Very little account is given of the lepers themselves before the injections, but photographs before and after the treatment are appended, and on the charts it is stated that they were all well marked, but not far advanced, cases of tuberculated leprosy. The patients were weighed and their urine tested before the injections were commenced. The dose began at half a milligramme, and was increased daily, and in four out of the five no reaction ensued until two milligrammes were reached. In the fifth case reaction followed one milligramme twenty-four hours after injection, when he had severe shiverings for three hours, general pains, and weakness, but no rise of temperature; indeed, in four out of the whole five the rise of temperature was slight as a rule, but in two cases it reached 105° F., on single occasions. As a general result there was some shrinking of the nodules, an improved sense of well being on the part of the patient, an increase of weight, and general improvement. There were no bad symptoms as regards the urine. Three had a miliary papular rash, and two had a vesicular eruption round the umbilicus. Dr. DE VALENCÉ thinks that if carried out in alternation with large doses of chaulmoogra oil, most gratifying results would be obtained.

It must, however, be borne in mind that these experiments were made in May, 1891, and that since then many other observers have recorded their experience, which is unhappily not so favourable as Dr. DE VALENCÉ'S was at the end of his investigations, and it would be desirable to know if the improvement obtained by him was temporary or permanent. D. G. DANIELSSEN treated fourteen lepers in Bergen with tuberculin. Five had anæsthetic leprosy, three had the pure tuberculated form, and six had the mixed or tuberculo-anæsthetic form. The experiments were carried on during four months. The commencing dose was one milligramme, and in some of them as much as 320 milligrammes for a dose was reached. The injections were made daily, unless the reactions were severe, when an interval of several days was allowed. In some of the cases the treatment had to be stopped even when only small doses had been reached, because the eruptions in the tuberculated and in the anæsthetic cases became so intense that the disease was evidently aggravated in the same way as used to be observed when iodine preparations were employed; but no case was fatal. This aggravation receives an explanation in the investigations made by Dr. LOOFT, Dr. DANIELSSEN'S assistant, who examined the blood for bacilli both before and after the injections; and, while he never found any before the injections, he did afterwards in several cases, and as far as could be observed they showed no signs of degenerative changes. It appears, therefore, that the tuberculin acts upon and breaks up the diseased tissue which contains the bacilli, and they thus get freely into the circulation. The general reaction came on usually from four to six or twelve hours after injection—occasionally, however, not till after two or three days; the local reaction occurred later. Drs. BABES and KALINDERO in their cases, however, found the reaction did not occur as a rule until twenty-four hours after injection. Unfortunately the conclusion drawn was that tuberculin aggravated the disease considerably, and, by setting free the bacilli, started fresh foci of disease, and made the whole process more active. As in lupus and phthisis, the patients became tolerant of the tuberculin after a time; but the disease progressed all the same, and fresh symptoms were frequently excited; many also of the old lesions became red and sensitive. In the anæsthetic form the patches enlarged, became redder and more sensitive, and new patches appeared.

In a case reported from a military hospital in Japan of a tuberculated leper the nodules diminished in size, and a certain amount of sensibility returned; but these good effects were only temporary, and the patient was losing ground at the time of the report.

Drs. BABES and KALINDERO of Bucharest treated seven cases. Their report, as far as it went, is fairly favourable, but some of their conclusions are not quite in accord with those of other observers. Thus they say that a rather stronger dose is required to produce a febrile reaction in leprosy than in tuberculosis; they find that the interval before the reaction is also much longer, as already mentioned (this is, perhaps, a question of dose). In other respects, they agree with others in stating that the fever lasts longer and the secondary reactions are more frequent, that cumulative action may be observed if daily injections are given, and that the local reactions may be absent, less marked, or late in development. In nerve leprosy local reaction was only once established, and there the anæsthesia was replaced by hyperæsthesia. This is a different result from that observed in Dr. COLCOTT FOX'S patient, treated by Mr. CHEYNE at King's College Hospital, in whom injections of 0·01 were followed by severe pains in the ulnar nerves, and in the calves and knees, with a temperature of 103° F. After the fourth injection extreme and dangerous collapse followed the reaction, the eruption became more prominent and large, blebs formed on both feet, and there were other unpleasant symptoms, so much smaller doses were subsequently given. All these symptoms occurred in a purely non-tuberculated case of long standing which was almost quiescent, obscure pains at intervals being the only symptoms left; the injections therefore had obviously excited a neuritis and revived the typical macular eruption which had faded away. The ultimate result, months after the cessation of the injections, was slight improvement; the patient asserted that she could open her hand better, that the anæsthesia was decidedly less, and that she herself felt better, had increased in weight, and the pains had not recurred. Curiously enough, Dr. POWELL of Cachar, in India, tried it in three well-marked tuberculated cases with absolutely negative results as regards reaction and everything else, even with doses of twelve milligrammes; while, to prove that the fluid was not at fault, two milligrammes injected into a lupus case produced characteristic local and general reaction. Dr. MORROW and Dr. FOX of New York also met with negative results in one case each, even with 20 milligrammes in Dr. MORROW'S case, except that it revived a

pruritus which had become quiescent. Dr. GOLDSCHMIDT of Madeira treated five cases—four tuberculated and one non-tuberculated—with the fluid, and always found that doses of one milligramme and upwards caused general and often local reaction. In one case intense and prolonged reaction ensued, followed by blebs and new swellings of skin and mucous membrane, while on the lower limbs absorption of the leprous infiltration was produced. His general conclusion was, on the whole, favourable; but he said that its use required great caution. Mr. CANTLIE of Hong-Kong used it in seven cases, and he also found bacilli in the blood after injection, there having been none there before. According to this observer, when the leprosy is advanced depression instead of elevation of temperature is produced. Dr. ABRAHAM'S case was ultimately neither better nor worse. In Dr. RADCLIFFE CROCKER'S case a single injection of two milligrammes excited an attack of leprous fever, which lasted three weeks. Scores of new tubercles came out all over the body, but under gurjun oil inunctions they all disappeared again, and there was a little less infiltration in some parts. The patient, a tuberculated leper, had previously improved considerably with large doses of chaulmoogra oil, and had had no febrile exacerbation for two years prior to the injection. As an ultimate result he was not really any worse; but three weeks' fever was a long price to pay for a single injection, and he did not care to have it repeated.

The above cases do not exhaust the list of experiments, but they are sufficient to show that tuberculin is very uncertain in its immediate effects on leprosy; that while in some it produces no reaction or effect at all, in others, even with small doses, considerable and prolonged reaction may ensue; and that therefore not more than one milligramme should be given at first, and cautiously increased according to the patient's toleration of the fluid. Secondly, that it revives the activity of cases which have been quiescent for a long time, producing neuritis, bringing fading rashes into prominence, exciting bullæ, and setting free the bacilli; these may get into the circulation and produce fresh cutaneous and other lesions. In the ultimate effect, while some patients have shown improvement that has not been proved to be permanent, and in some was certainly only temporary, on the whole the position may be summed up by stating that, as far as the results hitherto obtained are concerned, the improvement which may result is too uncertain, too limited in character and time, and purchased at too great a risk of aggravation of the disease by the dissemination of new foci, for it to be recommended as a treatment for leprosy; and although some of Dr. HUNTER'S or similar modifications of tuberculin might lessen the immediate disagreeable effects, the fact of its action being to set free bacilli rather than to destroy them should make us seek in another direction for remedial agents for the relief of victims of this much-dreaded disease.

FOR a long time the thyroid gland was a *noli me tangere* for surgeons, and its removal or free surgical treatment was regarded as a very hazardous procedure. Hæmorrhage was the dreaded complication, and the very free vascular supply to the organ, as well as its proximity to large and important arteries and veins, sufficiently explained the surgeon's dread of incising or excising it. For some years, however, patient and careful attempts have been made to deal with the various diseases of this gland in accordance with accepted surgical principles. It has been excised hundreds of times, division of the isthmus has been freely practised, cysts in its substance have been incised and drained, and solid growths have been enucleated from the healthy glandular tissue. Where total excision of the thyroid was largely practised evidence was soon forthcoming to show that such an operation was liable to be followed by very grave constitutional disturbance. J. L. REVERDIN was the first to call attention to this subject in 1882; but it was not until the appearance of KOCHER'S well-known paper in 1883 that the matter attracted the notice it deserved at the hands of the profession generally. Further investigation, experimental and clinical, has only corroborated REVERDIN'S and KOCHER'S statements. Total extirpation of the thyroid gland has therefore been once more placed in the list of operations to be performed only under very special circumstances, and where no other means of relief is available. Simple division of the isthmus, either by the knife or cautery, has been often successful in relieving compression of the trachea due to bronchocele, and has in some cases been followed by wasting of the enlarged gland. This result cannot, however, be relied upon, and for that reason the procedure is not wholly satisfactory. Injection has long been practised for cystic bronchocele, and the late MORELL MACKENZIE perfected this operation. He used a solution of perchloride of iron, introduced through a special cannula, and retained until acute suppuration had been set up. This inflammation is a serious matter, as is evidenced by the rise of temperature to 103° and even more. This treatment has been largely successful, but it has two obvious drawbacks: it makes the patient very ill, at any rate for a time, and the cyst may take some time to close. More recently these cysts have been incised and drained, the cyst wall being sutured to the skin. Two arguments have been urged against this method: the danger of hæmorrhage from the interior of the cyst, and the fact that greater scarring of the neck is involved than in the treatment by injection. In the majority of cases there is no notable hæmorrhage, but it is well known that the vessels running in the wall of the cysts may be of enormous size and have very thin walls, and then, from the sudden relief of tension in the cyst, is liable to be followed by very abundant bleeding. This can always be arrested by carefully plugging the cyst with strips of aseptic gauze or lint. If the operation is performed with antiseptic precautions and a clean dissection made down to the cyst, the sutures being placed neatly afterwards, only a very fine linear scar, which ultimately becomes almost imperceptible, results.

For the treatment of solid growths of the thyroid gland enucleation is rapidly taking the place of extirpation. So long ago as 1849 PORTA pointed out that distinct tumours occurred in the thyroid gland, which, although embedded in the tissue of the gland, could yet be shelled out from it, and he recorded a case in which he had followed this method. SOCIN of Bâle has practised the treatment by enucleation, and has brought it prominently

Digitized by Google

before the profession. Of late this plan of treatment has steadily gained in favour, and its applicability has been found greater than was at first thought possible. In the current number of the *Revue de Chirurgie*, A. REVERDIN records his last fourteen operations for goitre, and in no less than seven he resorted to enucleation of the growth in preference to partial excision of the gland. Of the seven earlier cases, only one was treated by enucleation, but of the last seven no less than six were submitted to this process. This was not due to a change in the nature of the cases, but to REVERDIN'S growing preference for and confidence in enucleation as he became more familiar with it. While recording these cases, he discusses the details of the operation. He recommends the exposure of the thyroid gland by a single straight or oblique incision extending the entire length of the tumour. If it is found that more room is needed, other incisions can be made later; but, as a rule, a linear incision is sufficient, and is much to be preferred to a flap wound of any kind. The muscles over the tumour must be cut, and the ends carefully raised and turned aside. When the thyroid gland is exposed the outer surface is often crossed by large and thin-walled vessels, and some of these will need to be carefully divided between two ligatures in order to expose a surface large enough to admit of the removal of the tumour. These vessels are so tender that if not handled very gently with forceps they tear and give rise to troublesome hæmorrhage. The tumour is then cut down upon by a series of careful incisions carried through the gland tissue over it. The exterior of the capsule of the growth can be distinguished from the rest of the gland. With his finger, if possible, the surgeon quickly isolates and then removes the tumour. This should be done as quickly as possible, and the surgeon will derive great help from a good assistant. Hæmorrhage may be very free, and the bleeding vessels must be seized with forceps and carefully tied, while smaller vessels may be controlled by sponge pressure. The divided muscles must be carefully stitched together, and the edges of the skin incision brought into apposition, after making due provision for the drainage of the cavity left. The patients often make a very rapid recovery from this operation. REVERDIN allows them to get up within a few days, and does not think it so important to keep the head at rest in the horizontal position as to gain the advantages in respiration and circulation that the upright position affords. When repeated injections of iodine or of similar irritants have been made into the tumour, enucleation may be impossible owing to the inflammatory process which the irritant excites, causing adhesion of the tumour to the surrounding glandular tissue. In such cases partial extirpation of the thyroid gland is the only operative means available.

THE Wandsworth District Board of Works has resolved to recommend the Local Government Board to insert a clause in the by-laws of the Public Health (London) Act to compel the occupiers of houses to cleanse their water cisterns once every six months, and to compel the owner of the house to place the cistern in such a position as would be easily accessible to the tenant.

"Ne quid nimis."

A CORONER ON UNQUALIFIED ASSISTANTS.

A VERY sad case is reported from Luton—the death of a young unmarried woman in lodgings after giving birth prematurely to a child. According to the evidence, on Wednesday, March 16th, she was not very well, and did not get up. Between two and three in the afternoon she said something which resulted in her landlady finding indications of the birth of an infant. On the Thursday she got up and came downstairs. In the night she seemed ill, with pain in her head. On the Friday evening she began to be delirious and wandering. The landlady then suggested the attendance of a medical man, and the patient expressed a preference for one from Dunstable, "Dr. Beart," whom, it transpired, she had consulted on several previous occasions. The landlady went to see "Dr. Beart of Dunstable," and explained what had happened, and he gave her a bottle of medicine, and told her if the patient were not better on the Saturday to let him know, and he would come and see her. She was worse on the Saturday, and the landlady sent a note to "Dr. Beart," and he came over in the evening and gave a prescription. After this medicine the raving ceased, and she slept a good deal in a semi-conscious way. On the Sunday a neighbour said something which induced the landlady to send for Dr. MacArthur, who found the patient in a dying condition, and she did die in an hour. At the inquest "Dr. Beart" said he was assistant to Mr. Henslowe, physician and surgeon, Dunstaple, and that he was not registered as a medical practitioner. He had resided at Dunstable for twenty-five years, and was formerly assistant to Dr. Hicks. When the jurors began to investigate the qualifications of "Dr. Beart," the coroner said they were going into matters outside the duties of coroners. We should not have thought so. The coroner then said: "They then came to the question whether she was properly treated by Mr. Beart. Well, he had known Mr. Beart for several years; he was a man who had had considerable experience, and he believed experience in midwifery cases. He in his evidence had stated that he was acting as assistant to Dr. Henslowe at Dunstable. "You can understand, gentlemen," remarked the coroner, "that I can approach this question without the slightest bias or the slightest professional feeling in any way whatever. Now it is a common, a very common, case, where a medical gentleman is called for him to send his assistant, and in nine cases out of ten the assistant is not what we call a qualified registered practitioner. He simply goes and attends the patients, and tells his principal on his return what he has done, and you may generally assume that he has done what is correct, for he would not be employed as assistant to a medical man unless he had had a considerable amount of experience as a dispenser and in other ways." He added that he thought the young woman seemed, as far as he could judge, to have had all the attention that she could have from the time of her confinement, and he submitted that she died a natural death. He thought it totally unnecessary for him to order a post-mortem examination, &c. Does the coroner know that the employment of unqualified assistants, as in this case, at a distance from his principal, who has never himself seen the case, is regarded by other coroners with the greatest dissatisfaction? It would be wrong to censure Mr. Henslowe on the evidence of so weak an argument as that used by the coroner; but his connexion with "Dr. Beart," and his non-appearance from first to last in a case so grave, ostensibly under the charge of "his assistant,"

A CORONER ON UNQUALIFIED ASS

A VERY sad case is reported from Lou young unmarried woman in lodgings was prematurely to a child. According to the Wednesday, March 16th, she was not very not get up. Between two and three in the said something which resulted in her ass indications of the birth of an infant. She she got up and came downstairs. In the course ill, with pain in her head. On the Sun she began to be delirious and wandering. It then suggested the attendance of a medica the patient expressed a preference for the "Dr. Beart," whom, it transpired, she had several previous occasions. The landlady went Beart of Dunstable," and explained what and he gave her a bottle of medicine, and the patient were not better on the Saturday he and he would come and see her. She was Saturday, and the landlady sent a note and he came over in the evening and gave After this medicine the raving ceased, and she deal in a semi-conscious way. On the Sunday said something which induced the landlady to MacArther, who found the patient in a critical she did die in an hour. At the inquest "Dr. Beart" assistant to Mr. Henslowe, physician and surgeon and that he was not registered as a medical had resided at Dunstable for twenty-five years formerly assistant to Dr. Hicks. When the coroner investigate the qualifications of "Dr. Beart" and they were going into matters outside the scope We should not have thought so. The coroner then came to the question whether she was seen by Mr. Beart. Well, he had known Mr. Beart years; he was a man who had had considerable and he believed experience in midwifery cases; evidence had stated that he was acting as Dr. Henslowe at Dunstable. "You can exclude men," remarked the coroner, "that I am sure question without the slightest bias or the professional feeling in any way whatever. Now a very common, case, where a medical person for him to send his assistant, and in nine cases the assistant is not what we call a qualified titioner. He simply goes and attends the patient his principal on his return what he has done generally assume that he has done what is right would not be employed as assistant to a medical he had had a considerable amount of experience and in other ways." He added that the young woman seemed, as far as he could have from all the attention that she could have had confinement, and he submitted that she died death. He thought it totally unnecessary to a post-mortem examination, &c. Does the that the employment of unqualified assistants case, at a distance from his principal, should seen the case, is regarded by other coroners dissatisfaction? It would be wrong to Henslowe on the evidence of so weak a that used by the coroner: but his non "Dr. Beart," and his non-appearance [illegible] are facts that require elucidation from him. Such a death is a tragedy that has happened before and will happen again. According to the *Luton Reporter*, the Home Office is to be communicated with on the subject.

LORD WANTAGE'S COMMITTEE.

THE evidence, which is very voluminous, taken before the committee appointed by the Secretary of State for War to inquire into the terms and conditions of service in the army, has just been issued in the form of a large Blue-book. It appears to bear out very much what we have already said on the subject. It is not so much from the evidence of generals and other officers of high rank as from that given by the non-commissioned officers and privates that the most valuable information is to be obtained as to the requirements of the rank and file. They are, after all, the persons principally concerned. The root of the matter with them is briefly this: that they want a clear shilling a day and free rations, and had enlisted under the impression that they would get this, but do not. We are glad to notice that the subject of unnecessary night duties has not escaped attention. Their prejudicial effect on health is generally admitted, and there is really no good object attained by multiplying sentries in various directions, as is the case at present. Now that the Duke of Connaught has called attention to the matter in connexion with the Guards, perhaps something will be done. It has always seemed to us that there is too much separation between the civil and military classes; they do not know one another enough—and are not sufficiently amalgamated. A good deal of the popular prejudice against the army is simply the result of ignorance. There is no reason why military bands should not play inside barrack-squares and the general public be encouraged to walk about the grounds and listen to the music. The old spirit of an objectionable kind of militarism may still remain in some continental nations, but it does not exist and has no force in this country. The army is a voluntary one, and is maintained for the good and defence of the nation. The greater the social intercourse between the civil and military classes, the greater will be the amount of sympathy, friendliness, and mutual respect between them.

COMPETITIVE DIETARIES.

THE great Roman general, Corbulo, we are informed by Tacitus, was in his Armenian campaign reduced to extremities, his army having suffered, not indeed from losses in battle, but from being driven to satisfy its hunger from the flesh of sheep. To the average Briton into whose dietetic cult the mutton-chop enters so largely, this announcement must seem inexplicable; so much so that he might be excused for thinking lightly of the stamina or pluck of his forefathers who allowed themselves to be conquered by soldiery for whose stomachs the flesh of sheep was too strong. The fact is, however, as Tacitus has stated it; and we know from other authorities that animal food as a constant element in the Roman soldiers' fare was found hurtful to his health and efficiency. Cæsar, in his Gallic war, tells the same story: "Ut complures dies milites frumento caruerint et pecore extremam famem sustentarent" (how for several days his troops did without corn-meal and sustained the extreme of hunger on mutton). Corn-meal was the grand necessary of life to those legionaries who, led by Cæsar, subdued the world, and who counted themselves starved, and were apt to mutiny if reduced to the "famine fare" of animal food. Even British troops have been known to suffer from an exclusive meat diet, as indeed we found to our cost in the Zulu campaign of 1879; while the preference of the Roman soldiery for vegetable food has its justification in the experience of the Russian army, and still more of the German one in 1870, which carried that memorable campaign to its triumphant close on the *Erbswurst* (pea-sausage flavoured with a little bacon). Without for a moment lending countenance to the vegetarian who would cut off butcher's meat from human consumption, we may concede to him that an animal diet, unbalanced by a due proportion of the "kindly fruits of the earth," is distinctly prejudicial to the consumer, particularly to the resident in cities, whose opportunities of open air exercise are few and far between. We are still in want of such a series of experiments on the nutrient and sustaining values of foods, vegetable and animal, as the late Professor Parkes of Netley instituted with such conclusive results on the various kinds of drink, from water up to spirits. Till statistics of equal comprehensiveness and accuracy are furnished us we must be content to remain imperfectly informed as to the competing claims of the two great factors of solid alimentation. In the half light we possess on the subject we must expect partisanship on either side—the vegetarian insisting on the exclusive virtues of his special diet and his carnivorous antagonist appealing to physiology and personal experience in favour of butcher's meat. "Competitive dietaries" are thus forced on a bewildered public, and the physician is often called in to repair the damage done to themselves by those who, on either side, have had too much "the courage of their convictions." That men and women should be trained to become "the intelligent custodians of their own health," as Sir James Coxe so well expressed it, must always remain a pious opinion till science and experience have authoritatively pronounced themselves on the due balance—not antagonism—between the animal and vegetable factors of daily food.

EPILEPTIC COLONIES.

IN the current number of the *Journal of Mental Science* Dr. C. Theodore Ewart discusses in an interesting manner the ever-present problem, What is to be done with epileptics? The question is discussed principally with reference to the working of epileptic colonies, in the establishment of which this country has taken so far scarcely any practical steps and Dr. Ewart's paper is an important contribution towards the solution of the problem. After describing the various efforts which have been made in other countries to grapple with this subject, he summarises the main principles which he thinks should be observed in the organisation of such a colony. The first essential is land, to consist of at least 500 acres of farm and woodland, well adapted to agricultural and horticultural purposes, within easy access of a large city, which would naturally supply a market for the produce. Then there must be small buildings, arranged in separate divisions for the male and female patients, each of the divisions to make provision in separate cottages for the demented, the convalescents, the school children, the workers, and the private patients of the higher classes. Medical care of each patient must be provided for, and there must be educational provision for epileptic children, and workshops, farm buildings, dairy, &c., for the adults, as well as a special laboratory for the study of epilepsy by a skilled pathologist. The two arguments advanced against the establishment of two types of asylums are that there would be a sameness of occupation, a want of hope, and an absence of object, calculated to drive a sane man into insanity in a short time. To this argument Dr. Ewart replies that in such a colony as is proposed there would be neither lack of objects nor absence of hope. The second argument touches the financial question, for it might be said that the drafting off of chronic cases would necessitate the introduction of a larger number of sane workmen and workwomen. To this Dr. Ewart's reply is that the welfare of the patients must be the first duty of a committee,

Digitized by Google

and he protests against the idea that the chronic cases are incurable. Even if they are, that is no reason why they should not be made useful, as such a course would give them an interest in life which, to say the least, would tend to ameliorate their condition. Besides, by separating the acute from the chronic, each class is placed in better circumstances for rapid recovery; the time of lodgment would thus be shorter, and the expense correspondingly lessened. This great problem is one which must be faced; it is obtruding itself more and more every day, and if by the means proposed we can in any way lessen the misery and brighten the lives of many of our fellow-men and women, while we protect the helplessness of childhood, and develop it into something better and more useful than under present conditions it has the chance of attaining, it is our duty, and it ought to be our pleasure, to make the attempt, even if it may entail at the commencement some sacrifices. But even from the economic point of view such a course will in the end bring its own reward.

THE LONDON COUNTY COUNCIL AND LODGING-HOUSES.

WHETHER we regard it from a social or a sanitary standpoint, the question of the licensing and regulation of common lodging-houses is and must be a matter of increasing public interest. Their growth is a necessary consequence of the influx into towns of a numerous working population, and their cleanly and otherwise efficient management is of course essential to the welfare of the whole community. We need not feel surprised, therefore, that the London County Council, as a responsible civic body fresh from its promises to the electorate, has thus early devoted a share of its attention to this question. At present the control of lodging-houses is vested in the hands of the police, an arrangement which is connected with obvious advantages of supervision. This control the Council would prefer to have transferred to itself, and it was in order to further its views on the subject that a deputation of its members recently waited upon the Home Secretary. The interview, though, as might have been expected, not decisive of any practical issue, is noteworthy as roughly indicating the grounds of a future settlement. The right hon. gentleman, we gather, would have no objection on sanitary grounds to the transference of the powers above mentioned. He freely admitted the excellence of the administrative machinery available for this department of the Council's work. At the same time, however, he recognised the necessity of reserving to the police authorities the practically unlimited power at present possessed by them of entry into *lodging*-houses. Little more, if anything, remains to be added to these arguments. The social and sanitary interest of the Council in establishments of this class is in no way incompatible in its exercise with that of the police, which is primarily and mainly judicial. We know of no reason why each of these authorities, as being most efficient in its proper sphere, should not exert its legitimate influence within that sphere in parallel association with the other.

NITROGENOUS ASSIMILATION.

THE effect of various forms of treatment on the assimilation of nitrogen has been studied by some of the recent candidates for the M.D. degree of the St. Petersburg Medico-Chirurgical Academy. Dr. Yaroff found that by regularly washing out the stomach the assimilation of the nitrogenous principles of food was increased, and where there was chronic gastric catarrh with constipation, these conditions were cured. He remarks, however, that for this result to be obtained it is essential that the patient should be accustomed to the use of the œsophageal tube, so that it can be introduced without difficulty. Tables are given showing the weight of different kinds of food, and of the nitrogen contained in each, together with the amount of fæces and urine, and their nitrogen, from which the percentage assimilated and metabolised is deduced. The assimilation was always higher by 2 or 3 per cent. during the week the washing-out was carried on than during the succeeding week, the metabolism on the other hand being generally lower—once as much as 20 per cent.—though occasionally slightly higher. Dr. Velichkin found that while hot-air baths were being taken the assimilation of nitrogen always improved, the average increase being over 2 per cent., and in most of the cases some increase on the normal amount was observed for several days after the baths had been discontinued. The baths likewise increased the nitrogenous metabolism on an average about 4 per cent. Dr. Sevastyanoff administered warm salt baths at 95° F. to phthisical patients, and found that the assimilation of nitrogen was increased, not only while the baths were being given, but also after they had been discontinued. As to the nitrogenous metabolism, it was increased quantitatively both during and after the baths, but, qualitatively considered, the change was lessened. Dr. Yavein, during observations on healthy persons, found that large doses of bicarbonate of potash somewhat diminished the nitrogen assimilated, citrate of potash having no effect. Both these substances, when given in considerable quantity, slightly increased the nitrogenous metabolism. It was noticed that while either of them was being taken the weight of the body increased, though it subsequently fell. This increase appeared to be due to an accumulation of water in the system, which was afterwards lost by increased secretion.

A CURIOUS SITUATION FOR A GOLD STOPPING.

AT a recent meeting of the Odontological Society, Mr. Newland-Pedley showed a dry specimen of sequestrum from the buccal surface of the alveolar process, in which a gold filling had been inserted. The patient presented herself complaining of a little hole in her gum, from which there was an offensive discharge. She said there had been a gumboil over the root of an upper back tooth which had led to the existing condition. The patient had consulted her dentist about a disagreeable discharge, and about fifteen months ago he inserted a gold filling in the little hole in the gum. On examination it was found that a gold filling was inserted in necrosed bone, and with the aid of a little cocaine a small sequestrum was removed with the filling *in situ*. It appears that the dentist had drilled into the alveolus between the two buccal roots. Was the necrosis due to this operation or of prior existence?

THE MONGOLIAN EYE.

IN the *Boston Medical and Surgical Journal* of March 3rd, 1892, is an abstract of a paper by a Japanese medical man published in the *Sei-I-Kwai Medical Journal* of Dec. 26th, 1891. This observer has studied in detail the differences between the characteristic eye of the Mongolian nations and of the Caucasian race. The difference between the two is caused neither by the size of the eyeball nor the colour of the iris, which is the same in both, but results from the shape of the eyelids. The epicanthus, a fold of the skin covering the inner canthus, is rare in adult white persons, but exists physiologically among the Japanese, so that it is sometimes called the Mongolian fold. In the majority of cases this fold runs obliquely inwards and downwards from the upper lid, so that the inner canthus is not round, as in white people, but sharp. When the fold is large it spreads to the inner part of the

lower lid, in which case the upper lid does not cross the cornea horizontally, but obliquely, giving the peculiar expression to the eye often met with in Japanese. Another peculiarity of the upper lid in Mongolians is the lack of development of the orbital furrow, the groove below the eyebrows. The skin covering the upper lid is very loose, so that when the cartilage is raised the skin is thrown into a transverse fold. When this fold is well developed it droops slightly over the margin of the lid. This interferes with the eyelashes, directing them downwards instead of forwards. In Japanese the cilia are short and straight. On the lower lid they are sometimes so badly developed and so few in number that they appear at first to be absent. When well developed they are sometimes bent inwards by the peculiar formation of the upper lid, and may seriously irritate the cornea. Except for this there is no great difference in the lower lid of Mongolians and Europeans. The margin is generally more curved in white people, so that there is often a portion of the sclerotic exposed between the lid and the cornea, a peculiarity, the author remarks, which makes "their eyes looking apparently upwards generally." As the skin of the lid is less firmly connected to the subjacent tissues in the Japanese, entropion is more common, but ectropion less common, among them than among Europeans.

SURGEON CAPTAIN G. E. HARE, D.S.O.

We are glad to congratulate Surgeon Captain G. E. Hare, of the Medical Staff, on his being appointed Companion of the Distinguished Service Order, in recognition of his services during the operations against the Kachins and in the Wuntho District, Upper Burmah. It can never be said that officers of the Medical Staff are wanting in gallantry when the opportunity occurs, and when calls are made upon their sense of duty under the circumstances in which they frequently find themselves in the field.

EFFECTS OF CHLOROFORM INHALATION ON THE BLOOD AND URINE.

Dr. Sokolovski has published some observations on the hæmometrical and morphological changes in the blood occasioned by the inhalation of chloroform. He examined specially nineteen cases, which he divided into three categories, according as there was no blood lost, an appreciable quantity of blood lost, or the narcosis was of long duration; he observed the blood at regular intervals. He found that during the first few hours after the chloroformisation the actual number of young or immature white corpuscles was diminished, though not to a very marked degree—e.g., in one case their number per cubic millimetre fell from 1743 to 1300; the number of mature corpuscles, on the other hand, always increased. The increased number of white corpuscles during the early period appeared to be due to an increase in the multinuclear hypermature "neutrophil" elements, the number of which in the case above referred to increased from 5395 to 14,805 per cubic millimetre, so that the morphological metamorphosis of the blood increases in the sense of a change of elements to the latest stage of their existence. Later on, from the second day, the actual number of white corpuscles begins to diminish, and goes on diminishing, and may continue to do so for as long as ten days, until it has fallen to normal. During the whole of this period not only the actual number of immature and even of mature white corpuscles, but their number as compared with the hypermature, increases, while the number of the latter diminishes, falling ultimately sometimes below the normal for a time. This chloroform leucocytosis or lymphocytosis may be analogous to that due to certain other drugs as camphor, turpentine, or cocaine, or to that occurring in certain febrile conditions—relapsing fever or pneumonia. The temporary increase of the immature and mature mono-nucleated elements may be, according to Dr. Sokolovski, regarded as a true reaction on the part of the lymphatic and hæmatopoietic organs, due to the stimulation produced by the diminished number circulating during the chloroform narcosis. Another Russian observer, Dr. Sokoloff, who investigated the effect of chloroform inhalation in both man and animals, found that in most cases a minute amount of albuminuria occurred, which, however, soon disappeared. In some of the human subjects there was also a slight amount of peptone in the urine.

THE REPORT OF THE VACCINATION COMMISSION.

It is understood that in their forthcoming report the Commissioners will recommend the abrogation of cumulative penalties on persons charged with neglecting to have their children vaccinated. Attention will also be drawn to a point frequently overlooked—namely, that magistrates have a discretionary power in regard to the imposition of fines. In the Act of 1867, 30–31 Vic., cap. 84, it is provided that a person failing to comply with the regulations "shall be liable to a penalty not exceeding 20*s.*"; and in the amending Act of 1871, 34–35 Vic., cap. 98, the same phraseology is used.

THE ISLINGTON MEDICAL OFFICERSHIP OF HEALTH.

The Local Government Board have declined to sanction the appointment by the Islington Vestry of Dr. Wynn Westcott as temporary medical officer of health for Islington for six months in succession to Dr. Meymott Tidy, as being contrary to the by-laws of the vestry and without advertisement. It would have been a serious blow to the purity of local government if the Board had done otherwise. We shall not dwell on an incident so painful as this is. We can only rejoice that the local profession and the local press have together fought for the observance of the usual and obvious rules by which fair play and efficiency are secured in elections of responsible officers.

OCCUPATION FOR THE FEEBLE-MINDED.

From time to time we are reminded by its effects upon social or political conditions that the thinking power of Birmingham is not bounded in its applications even by the wide circle of its varied industries. Art and science have been appreciably indebted to its influence. It is, however, especially in the guidance and reform of civic and social usages that we are accustomed to trace the effects of this healthily active leaven. By way of illustration, we may mention a recent project which owes its rise to the kind originality of a ladies' committee. There exists in the hardware capital, as in other cities, a residuum of mentally weak but not incapable persons. Overmatched intellectually by the average man or woman, they have no definite position or sphere of usefulness among their neighbours, and are consequently as a rule dependent either on friendly maintenance or on parish relief. The committee already mentioned has taken account of these poor people, or more strictly, of the women among them, and has organised for them a system of profitable employment. This consists in the establishment of a laundry with adjacent cottage homes. The household and working expenses of the institution are to be defrayed partly by the earnings of the inmates and partly by subscriptions paid by their relatives or by parochial guardians. In this way their intellectual talent, however meagre, will be utilised, and it is at least probable that an effectual check will be placed upon the reproduction by such

Digitized by Google

persons of a progeny as lacking in parental care as in mental capacity. There is also a very fair prospect that the mere process of employment will do something to awaken and strengthen the dull faculties of these semi-imbeciles. Every true friend of his species will therefore wish well to the Birmingham experiment, which might even be extended to meet the case of half-witted men, and which, if successful, will certainly not fail to be repeated in the social usage of other communities.

HEALTH OF THE PRINCE OF WALES.

FROM time to time there appear in the lay press certain statements regarding the health of the members of the Royal Family, which the merest smattering of knowledge of anatomy and physiology would show to be unfounded. Thus, referring to the health of the Prince of Wales, it is gravely stated in one of our contemporaries that "several months ago much anxiety was caused by the presence of a clot of blood in one of the Prince's legs; and this anxiety was intensified by this clot travelling from one limb to the other." By what circuitous route the journey of the clot was performed, and how frequently the passage from the one side of the body to the other was undertaken, are wisely left without remark. The newspaper in question prefers to exercise itself with "annoyances and troubles which have recently fallen to his share." Here undoubtedly it is on safer ground. The Prince of Wales has suffered much from the calamity which recently befell the nation, and this has led to depression and to some weakness. Cessation from the very active life which he is accustomed to live has also naturally exercised an unfavourable effect on the Prince's general health. Since, however, he has been going about from place to place in the south of France with Prince George he has improved in general health and spirits. In fact, the most recent information from the south of France concerning the Heir Apparent is altogether reassuring, and he is said to be in better health now than he has been at any period since the death of the Duke of Clarence and Avondale. The statement about the "travelling clot" seems to be based upon a condition which arose during the now historical illness of the Prince of Wales. At that time he had an embolism, and that has caused the superficial veins to enlarge. Now and again he suffers from a slight phlebitis, which causes him some pain. Prince George is also better than when he left, though he still suffers from wakefulness and neuralgia. The Princess of Wales, who has suffered very much from shock and from natural grief, has in some degree recovered her spirits, and Princess Maud has recovered from her synovitis.

REVULSANTS AND THEIR EFFICACY.

DR. L. DEVOTO, in an interesting contribution to the *Gazzetta degli Ospetali*, shares Dr. Besson's conclusions as to the therapeutic value of "intense and rapid revulsion"—sinapisms, that is to say, in contradistinction to vesicants which represent the group of revulsants "permanent and slow." The former he finds useful in acute disease by their power of lowering the temperature, of slowing the heart's action, and of producing a general vascular dilatation. In chronic disease where is encountered a falling off of nutrition, "cutaneous excitation has the power of determining an acceleration of organic combustion," besides exercising a calmative effect, more or less enduring, more or less considerable, on the phenomenon of pain. In syncope, moreover, they re-establish pressure and arouse the cardiac function. As to the slow and feeble revulsion, of which the vesicant is nowadays almost the sole representative, Dr. Devoto's experience harmonises with that of Dr. Besson, for whom vesicants have but one indication—that of inducing anæmia of the subjacent tissue and relieving pain. In pneumonia their use is invariably negative or worse. They have no power over the pulmonary lesions or over its morbid symptoms. "They augment the hyperæmia, they favour the dyspnœa and hypostasis, they predispose to asphyxia, and while suppressing, it is true, the pain at a given point, they reproduce it at another." Not less useless has he found them in pleurisy, while in diabetes mellitus, he considers, they are absolutely contraindicated, equally so in aged subjects, in children, and, generally speaking, in all maladies the characteristic note of which is failure or feebleness of the powers.

THE ELEVENTH CONGRESS OF INTERNAL MEDICINE.

THE meeting of the eleventh Congress of Internal Medicine will take place at Leipzig under the presidency of Dr. Curschmann, from April 20th to the 23rd. The programme contains the names of many authorities of the highest order, and the subjects to be under discussion will be of much interest. Thus, Birch-Hirschfeld of Leipzig, and Ehrlich of Berlin, will read a paper on "Obscure Anæmic Conditions." Rosenstein (Leiden), one on "Chronic Inflammation of the Liver." Emmerich (Munich) will discuss the cause of immunity from infectious diseases, and Goltz (Strassburg) will give the results of observations made by himself and Ewald on the excision of large portions of the spinal cord in animals. Among the more eminent medical men who will take part in the Congress are Schott (Nauheim), Fürbringer (Berlin), Minkowski (Strassburg), Ebstein (Göttingen), Adamkiewicz (Krakau), Finkler (Bonn), Israel (Berlin), Klebs (Berlin), Buchner (Munich), Von Ziemssen (Munich), Löffler (Greifswald), Petersen (Copenhagen), and Unverricht (Dorpat). Paschmann (Vienna) will contribute a paper on "Influenza and its Relation to Dengue." Cornet (Berlin) will treat of Tuberculosis. Congress tickets can be obtained from Dr. Krehl, 31, Thalstrasse, Leipzig, for 15 marks, which will entitle to a copy of the Transactions. An exhibition of medical apparatus, instruments, and preparations will be held in connexion with the Congress in the theatre of the Crystal Palace.

RED CROSS CONGRESS IN ROME.

AN Italian correspondent writes: "I announced some weeks ago the international *festa* of the Red Cross in Rome to which representatives from all the signatory powers have been invited. The programme of the proceedings is now before me, and if the weather maintains the loveliness that usually characterises the month of April in central Italy, no material element will be wanting to success. On the evening of Wednesday, the 20th, the 'Congressisti' will be received in the Sala Umberto Primo, where the official presentations will follow. Next day, at 2 P.M., the inauguration of the International Congress will take place in the *salone* of the Palazzo dei Conservatori in the Capitol. The opening address will then be delivered by the president, Count Gian Luca della Somaglia, Senator of the Kingdom. To this a discourse in reply will be made by a delegat of the different foreign powers represented. On Sunday, the 24th, the King and Queen will entertain the congress at a banquet in the Quirinal Palace, and on the following evening there will be a 'serata di gala' (evening entertainment) at the Costanzi. Tuesday, the 26th, will be a very attractive day, on the evening of which there will be a grand reception of the 'Congressisti' in the galleries of the Capitoline Museum, illuminated for the occasion by flambeaux distributed among the *chefs-d'œuvre* of statuary standing out from a background of evergreens. The hosts

In the King and Queen will entertain the Congress banquet in the Quirinal Palace, and in the ing evening there will be a "serata" of ing entertainment) at the Costanzi Theatre. will be a very attractive day, on the occasion will be a grand reception of the Congress by series of the Capitoline Museum, illuminated by lambeaux distributed among the chief ding cut from a background of evergreens of the occasion will be the Syndic (the Duke of Sermoneta) and the municipal councillors. On the next day (Wednesday, the 27th) a special train will convey the 'Congressisti' to the falls of Tivoli. Arrived at that picturesque spot of the Sabine hills, the visitors will witness the improvisation of a 'treno ospedale' (hospital train), the transport of a mountain ambulance, and the disposal of all its departments on the Tivoli upland. Thereafter they will be entertained at a banquet of 150 covers in the superb Villa d'Este, kindly set apart for the purpose by his Eminence Cardinal Hohenlohe. Italy claims to have initiated the Red Cross movement, afterwards solemnly organised at Geneva under General Dufour, and on this occasion she will endeavour to show a hospitality which in another power would be neighbourly, but which in her case aspires to be parental."

SOURCES OF SYPHILITIC INFECTION.

DR. RASSLER, in his essay for the M.D. of the University of Kiel, makes a valuable contribution to the literature of syphilitic disease. The *Archiv für Dermatologie und Syphilis* states that Dr. Rassler undertook the labour of analysing 630 cases of syphilis treated in the medical clinic with the object of ascertaining the number arising from extra-genital infection. He found thirty-four such cases, comprising twenty-three of the lips, one of the tongue, two of the mucous membrane of the mouth, and three of the mamma. In three instances the primary sore occurred on the genital organs without connexion having taken place, and in the remaining two it was impossible to indicate the locality. The result of these investigations shows that 5 per cent. of all cases of syphilis are due to extra-genital infection. According to other authorities, the proportion varies between 1 and 10 per cent., except in certain parts of Russia, where the proportion is said to reach as high as 80 or 90 per cent.

THE CENSURE OF A WORKHOUSE MEDICAL OFFICER BY A JURY.

SOME time since we had occasion to notice the censure of the medical officer of a workhouse in the East-end on very insufficient ground by a jury for alleged inadequate attention to a dying patient. We expressed the opinion that the Local Government Board would ascertain the merits of the case, and see that its servants were fairly judged. This hope has been realised. The Board did not indeed make an inquiry, having found that there was no tittle of evidence against the medical officer, and, that being so, there was no ground for an inquiry as asked for by the board of guardians. The case affords another instance of the ease with which some boards of guardians and juries adopt a tone of censure towards medical men. It is gratifying to know that there is a court of appeal to which medical officers who are conscious of doing their duty can confidently look for fair judgment. It would be still more gratifying to be able to believe that guardians and juries will take a more reasonable view of the services of medical officers.

PARSIMONY OF PAROCHIAL AUTHORITIES ABROAD.

PARISH DOCTORS in all countries complain of microscopic remuneration for what in some cases is macroscopic labour. The Spanish parochial medical officers have recently been agitating more or less publicly for a better recognition of their services. The Belgian *médecin des pauvres*, too, does not seem to hold a very enviable position, if we may judge from a complaint that has just been published in *Le Scalpel*. From this it appears that the authorities of a certain manufacturing town containing a population of 8000, including 5000 working people, have offered the reduced amount of 1800 francs annually for attendance on the poor, including medicines and confinements. Hitherto the work has been divided between two local practitioners, who, although threatened with a public advertisement for a stranger, have agreed to decline the post. The authorities have carried out their threat, and advertised what at first sight seems a fairly attractive appointment for a young practitioner wishing to start in practice, yielding about five francs per diem; but for this an average of twenty-five visits is required, including, it must be remembered, confinements and medicines, which last cannot be bought, we believe, at wholesale druggist's prices, but must be obtained through a pharmaciet. The "twopence gross earnings per visit" is really a ridiculous sum to offer; and it can only be hoped that no Belgian medical man, however young and inexperienced, will come forward as a candidate.

PHARMACY ACT PROSECUTIONS.

THE reality of the powers conferred under the Pharmacy Acts has lately received a very practical demonstration in Glasgow. In a number of cases prosecutions have been instituted at the instance of the Registrar under the Pharmacy Acts, Mr. Richard Bremridge; in all cases the offence consisted in the sale of poisons by a person who was not a duly registered chemist. No one can complain that the poisons were not fairly selected. They consisted of oxalic acid, red precipitate, chloroform, ergot of rye, tincture of opium, and opium. The fines imposed were heavy, being the full penalty in most cases, together with costs on a high scale. Practically there was no valid defence in any of the cases, although it seemed that there was an erroneous notion that if the shop was visited daily by a qualified man the Act had not been infringed. In one case it appeared that the respondent attended medical classes in Glasgow during the day, that his sister kept the shop, and that a doctor visited it three times a day and remained an hour each time. The real owner of the shop was the respondent's brother, who was a musician. A few more such prosecutions, carried to a successful issue, would do much to safeguard the public against the dangers of the sale of poisons by unqualified persons.

THE COSTLINESS OF FALSE CERTIFICATES OF DEATH.

WE noticed a short time since an inquest on the body of Susannah Elizabeth Walker of Holloway. The case has been further elucidated at the North London Police-court, before Mr. Haden Corser. On Saturday last Mr. David Hyman Dyte, of Derby-street, King's-cross, and Pooles'-park, Holloway, was summoned for issuing a false certificate of death in contravention of the Births and Deaths Registration Act, 1874. And Henry Smythe, his unqualified assistant, was summoned for using the said certificate, well knowing it to be untrue. Mr. Charles Townley, superintendent registrar for the parish of St. Mary, Islington, prosecuted for the Registrar-General. The allegations were that the poor at a provident dispensary at 43, Pooles'-park were seen sometimes by a lady and sometimes by Mr. Smythe, and if a death occurred, Mr. Dyte signed the certificate without having previously seen the case. Mr. Townley had four such cases, but only pressed the present one. Mr. Dyte, through his barrister, Mr. Lyon, admitted the offence, but excused himself in this case on the score of illness. Mr. Lyon did not strengthen his case by showing how Mr. Dyte, though not seeing dispensary patients, saw the notes of them by his unqualified assistant. Dr. Charles R. Drysdale testified to Mr. Dyte's professional and general character and great ability. This did not alter the opinion of the judge that the highest penalty should be inflicted—a fine of £10 or a month's imprisonment, and £1 13*s.* 6*d.* costs.

Digitized by Google

Mr. Smythe at first pleaded not guilty, and denied having seen the certificate. But on being pressed he begged to withdraw the plea of not guilty. Thereupon a medical practitioner of Forest-gate, spoke of more than twenty years' knowledge of him as apprentice and assistant. He considered Mr. Smythe more competent than many qualified medical practitioners. Such testimonials are in very questionable taste, and they have nothing to do with the question of two persons, one qualified and the other unqualified, combining to give a false certificate and to conduct an essentially false practice. There is a certain aggravation in men who ought to know better doing such things. Mr. Corser fined Mr. Smythe £5, with the alternative of fourteen days' imprisonment, and £1 13*s.* 6*d.* costs. We have no wish to add to the pain which Mr. Dyte must feel in being placed in such a situation. But there is one obvious aggravation of the situation—that it is without excuse, and after very ample and repeated warning. We have pointed out time after time the risk incurred by medical men doing their work through unqualified assistants and signing false certificates.

OFFICIAL ANALYST TO THE HOME OFFICE.

THE appointment of official analyst, which will shortly be made, deserves the most careful consideration of the authorities. The duties of the post are primarily chemical; at the same time, we are of opinion that a man should be elected who has a deserved reputation as a medical practitioner. A chemist pure and simple, however learned and skilful he may be in his special branch of science, must necessarily lack to a great extent the knowledge of the relation of the action of poisons to the physiological functions and anatomical structures of the body. General descriptions are laid down in the text-books of the symptoms of poisoning and the appearances resulting from toxic and irritant agents, but the "history of the variations," which is a most important point in the investigation of cases of alleged poisoning, requires a wide and varied knowledge to turn it to trustworthy, practical use—a knowledge that can only be obtained by one who is a toxicologist in the most comprehensive sense of the term.

FINE FOR NEGLECT OF NOTIFICATION.

THERE have been several instances lately of medical men being fined for not notifying infectious diseases. At Guildhall on April 8th a gentleman was summoned under Section 55 of the Public Health (London) Act, 1891, at the instance of the Commissioners of Sewers, for that, on or about Feb. 19th, being the medical practitioner called in to attend a patient in Fleet-street, on becoming aware that he was suffering from small-pox, he unlawfully failed to send to the medical officer a certificate. The discovery of the case was made afterwards, when application for disinfection was made. The practitioner pleaded that being busy and having affliction in his own family the matter slipped his memory. The defence was intelligible but insufficient, and a fine of 40*s.* was imposed.

EXPERIMENTS ON THE CORD.

IN a series of experiments carried out by Dr. Mott and published in the *Journal of Physiology*, of which an abstract appears in a recent number of the *Neurologisches Centralblatt*, he found that pricks with a needle evoked a less prompt response on the side on which the cord had been cut than on the opposite side. Other tests also seemed to show that sensibility to pain, temperature, and pressure was less on the side on which the cord had been divided. No loss of sensibility was found on the same side. The knee-jerk was at first lost, later it was exaggerated on the affected side. The restoration of a movement was in proportion to its bilateral character and the height of the section. Flexion returned before extension, and movements at the hip before those at the knee and ankle. Toe movements returned only in slight degree, but motor power in other respects had in the space of two months so much improved that only very careful observation could distinguish a difference between the two sides. In the first week after the operation considerable disturbances, apparently vasomotor in character, were present on the side on which the operation had been done. Stimulation of the right hind-limb centre in the cortex of animals in which the left side of the cord had been divided caused movements of both hind limbs. The secondary degenerations were those usually described and no crossed descending degeneration was found.

FOREIGN UNIVERSITY INTELLIGENCE.

Rostock.—Dr. Oscar Langendorff of Königsberg has been invited to accept the chair of Physiology vacant by the death of Professor Aubert.

Jena.—Professor Stintzing has temporarily taken charge of the Medical Clinic. Dr. Verworn of Berlin has been recognised as *privat-docent* in General Physiology.

Helsingfors.—Dr. Schulten has been promoted to the full Professorship of Surgery; Dr. Ayrapää has been appointed to lecture on Odontology; Dr. Pipping has been promoted to an Extraordinary Professorship of Children's Diseases; Dr. Hjalmar Bonsdorf has been appointed to a Lectureship on Surgery. A Dental Clinic has been established.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.

THE deaths of the following distinguished members of the medical profession abroad have been announced:—Dr. Adolf von Stein, at the age of eighty-seven. He had been at the head of the medical department of the Wurtemburg army, and had also written a good deal on comparative osteology.—Dr. Karl von Schroff, Professor of Pharmacology in the University of Gratz, at the age of forty-eight.—Dr. V. J. Antonoff, Ordinator of the St. Petersburg Municipal Hospital and author of various papers.—Dr. Pippinskjold, Professor of Midwifery and Gynæcology in the University of Helsingfors. By his will he left £5900 for a lying-in hospital, £10,000 for the creation of a chair of physics, and £4000 to a widows' fund.

THE International Hydrological Congress, fixed to meet in Rome this year, has, by arrangement of its organising committee, been postponed till September, 1893, when the great International Congress of Medicine and Surgery will be held. The solidarity of the thermo-mineral department of the healing art, with the sister departments, will thus be recognised, to the great convenience of all who are interested in the newer as in the older developments of therapeutics.

WE regret to notice the death of Dr. Hayes Agnew of Philadelphia. Dr. Agnew was well known as a representative American surgeon; in this country he will be best remembered by the part he took in the treatment of the late President Garfield, and by his work on Surgery, which remains a monument of industry. He was a most enthusiastic teacher, and will be greatly missed from the chair of Surgery at the University of Pennsylvania.

A COURSE of instruction, clinical, anatomical, and pathological, is announced to be given at the Salpêtrière by Dr. A. Dutil, *chef de clinique*, and Dr. Paul Blocq, chief of the Pathological department, beginning on May 2nd. The course will be held four days a week for five weeks. The number of pupils will be limited. Application should be made to Dr. A. Dutil, at the Salpêtrière Hospital.

Digitized by Google

MR. F. J. M. PAGE, B.Sc., F.I.C., has been appointed to the chair of Chemistry and Physics at the London Hospital, rendered vacant by the death of Dr. Tidy.

IN Kazan there is an epidemic of typhus fever. More than ten of the medical officers of the hospitals have been attacked by the malady.

THE ROYAL COLLEGE OF PHYSICIANS.

THE Extraordinary Comitia held on the 11th inst. to elect a President was well attended. Before the election various matters of business had to be dealt with; but although these were numerous, they did not present any particular difficulty. A communication was received from the Home Office, acknowledging the address of condolence presented upon the death of the Duke of Clarence and Avondale. From the Foreign Office two communications were received: one suggesting a cure for snake-bites and a form of treatment for kidney disease; the other with reference to the practice of medicine by English practitioners in France. The latter was referred to the consideration of the committee. Communications were also received from the Colonial Office, and from the "Inebriates' Legislation Committee" of the British Medical Association. The College solicitors enclosed a printed statement of defence in the action now pending in the Chancery Division between the Royal College of Physicians (plaintiffs) and the General Medical Council (defendants), and it was announced that the case was now set down for hearing, and would, in all probability, come on next term. From the College of Surgeons a formal letter was received dealing with the question of fees to be paid to examiners, and with a small matter of detail connected with the schedule for examination under the new regulations for the five years' curriculum. Dr. Semon, on behalf of the Berlin Committee, presented to the College one of the Virchow medals struck on the occasion of the Virchow jubilee. The President announced that at the instance of the War Office a scheme for the examination of army medical officers had been drawn up conjointly with the Royal College of Surgeons, and had been forwarded to the War Office. A University Committee was appointed to consider and report from time to time on any proceedings relating to the formation of a university in London. The following representatives of the different medical schools were nominated members of this committee: Dr. Payne, Dr. Andrew, Dr. Pye-Smith, the Registrar (Dr. E. Liveing), Dr. Norman Moore, Dr. Allchin, Dr. Coupland, Dr. MacAlister, Dr. Mackenzie, Dr. Bruce, Dr. Cheadle, Dr. Priestley, and Dr. Barlow. The report from the Laboratories Committee was received; it indicated that there had been two new applications for permission to work in the laboratories, and that since the last quarterly report all but five who had previously been at work have applied for permission to continue their researches. Sir Andrew Clark then delivered the annual Presidential Address. At the outset he remarked that that portion which dealt with the history of the movement for the establishment of a new university in London as it concerned the College would be printed and circulated amongst the Fellows, even though he might not have time to read it. After referring to the great increase in the numbers of the Fellows, Members, and Licentiates during the past year, he spoke in feeling terms of the amount of labour that had fallen upon the Registrar, and the need, in the near future, of supplying him with some assistance. He made an appreciative reference to the work done in the laboratories, and also to the various lectures which had been delivered within the College. The arrangements which had been made for the revision of the Nomenclature of Diseases also received notice in passing. The cordiality of the relations existing with the Royal College of Surgeons and also with the various departments of Government was noted. The President then proceeded to sketch the careers of the following deceased Fellows: Sir Henry Cooper, Dr. Robert Martin, Dr. Henry Monro, Sir George E. Paget, Sir James Risdon Bennett, Dr. Henry Gawen Sutton, and Dr. William Henry Stone. The happiness of the eulogistic terms employed and the kindly appreciation evinced in most of these remarks elicited frequent applause. Passing to the questions at issue between the Royal College of Physicians and the General Medical Council, the President gave a brief account of the events which had led to the present difficulties and spoke with pardonable warmth of the action of the General Medical Council. Reference to the successful issue of the labours of the committee appointed to consider the five years' curriculum brought to a close an address marked by singular fluency and eloquence. The question of greatest interest to the College, the attitude assumed towards the proposed new University in London, must be considered at leisure when it appears in print, as it was unavoidably crowded out. The motion of a vote of thanks, moved by the Senior Censor and seconded by the Emeritus Registrar, was carried by acclamation. The election of President then took place. Sir Andrew Clark was elected for the fifth time, receiving 97 votes, there being 103 Fellows present, the remaining votes being divided between Sir Richard Quain, Sir Henry Pitman, Sir Dyce Duckworth, Dr. Wilks, and Dr. Sturges. It is a coincidence that the number of Fellows voting should be exactly the same as last year, when Sir Andrew Clark received 96 votes.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 5975 births and 4543 deaths were registered during the week ending April 9th. The annual rate of mortality in these towns, which had declined in the preceding three weeks from 24·8 to 22·2 per 1000, rose again to 23·3 last week. In London the rate was 22·2 per 1000, while it averaged 24·0 in the thirty-two provincial towns. The lowest rates were 12·3 in Croydon, 14·3 in Brighton, 15·4 in West Ham, and 16·0 in Birkenhead; the highest rates were 31·0 in Manchester, 31·1 in Oldham, 31·6 in Halifax, and 33·5 in Salford. The 4543 deaths included 493 which were referred to the principal zymotic diseases, against 435 and 427 in the preceding two weeks; of these, 172 resulted from whooping-cough, 163 from measles, 57 from diphtheria, 41 from scarlet fever, 31 from diarrhœa, 25 from "fever" (principally enteric), and 4 from small-pox. No fatal case of any of these diseases was registered in Plymouth; in the other towns they caused the lowest rates in Bradford, Gateshead, and Leeds, and the highest rates in Sunderland, Sheffield, Derby, and Wolverhampton. The greatest mortality from measles occurred in London, Sheffield, Birkenhead, Liverpool, and Wolverhampton; from scarlet fever in Preston and Cardiff; from whooping-cough in Hull, Derby, Sunderland, Blackburn, Sheffield, Salford, and Wolverhampton; from "fever" in Norwich and Preston; and from diarrhœa in Derby and Burnley. The 57 deaths from diphtheria included 34 in London, 4 in Sheffield, 2 in West Ham, 2 in Birmingham, and 2 in Wolverhampton. Two deaths from small-pox were registered in London, 1 in Croydon, and 1 in Halifax, but not one in any other of the thirty-three large towns; 39 cases of this disease were under treatment in the Metropolitan Asylum Hospitals, and 9 in the Highgate Small-pox Hospital on Saturday last, the 9th inst. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 1289, against 1226 and 1227 on the preceding two Saturdays; 166 new cases were admitted during the week, against 126 and 139 in the previous two weeks. The deaths referred to diseases of the respiratory organs in London, which had declined in the preceding three weeks from 523 to 430, further fell last week to 403, and were 26 below the corrected average. The causes of 75, or 1·7 per cent., of the deaths in the thirty-three towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Nottingham, Bolton, Leeds, Newcastle-upon-Tyne, and in nine

Digitized by Google

other smaller towns; the highest proportions of uncertified deaths were registered in Brighton, Liverpool, Preston, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns which had declined in the preceding three weeks from 24·2 to 21·2 per 1000, rose again to 24·1 during the week ending April 9th, and exceeded by 0·8 per 1000 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 18·6 in Leith and 18·9 in Perth to 23·2 in Aberdeen and 27·7 in Glasgow. The 671 deaths in these towns included 30 which were referred to whooping-cough, 14 to measles, 10 to diarrhœa, 5 to "fever," 4 to scarlet fever, 3 to diphtheria, and not one to small-pox. In all, 66 deaths resulted from these principal zymotic diseases, against 69 and 65 in the preceding two weeks. These 66 deaths were equal to an annual rate of 2·4 per 1000, which was slightly below the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of whooping-cough, which had been 34 and 24 in the preceding two weeks, rose again to 30 last week, of which 17 occurred in Glasgow, 5 in Aberdeen, and 4 in Edinburgh. The deaths referred to measles, which had been 12 and 15 in the previous two weeks, declined to 14 last week, all of which were recorded in Glasgow. The fatal cases of "fever," which had increased from 4 to 8 in the previous three weeks, fell last week to 5, and included 4 in Glasgow. The 4 deaths referred to scarlet fever and the 3 fatal cases of diphtheria also showed a decline from the numbers in the previous week. The deaths referred to diseases of the respiratory organs in these towns, which had been 181 and 158 in the preceding two weeks, were 160 last week, and were slightly below the number in the corresponding week of last year. The causes of 66, or nearly 10 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 40·1 and 37·3 per 1000 in the preceding two weeks, further declined to 33·0 during the week ending April 9th. During the thirteen weeks of last quarter the death-rate in the city averaged 38·4 per 1000, the rate for the same period being 28·2 in London and 19·8 in Edinburgh. The 221 deaths in Dublin during the week under notice showed a decline of 29 from the number in the preceding week, and included 23 which were referred to measles, 3 to whooping-cough, 1 to scarlet fever, 1 to "fever," 1 to diarrhœa, but not one either to small-pox or diphtheria. In all, 29 deaths resulted from these principal zymotic diseases, equal to an annual rate of 4·3 per 1000, the zymotic death-rate during the same period being 3·0 in London and 1·2 in Edinburgh. The fatal cases of measles, which had increased in the preceding three weeks from 12 to 24, were 23 last week. The deaths referred to whooping-cough, which had been 5 in each of the previous two weeks, declined to 3 last week. The fatal case of "fever" corresponded with the number in the preceding week. The 221 deaths in Dublin last week included 36 of infants under one year of age, and 59 of persons aged upwards of sixty years; the deaths of infants showed a decline, while those of elderly persons slightly exceeded those recorded in the preceding week. Four inquest cases and 5 deaths from violence were registered; and 66, or nearly a third, of the deaths occurred in public institutions. The causes of 23, or more than 10 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

IT is reported that Surgeon-Major-General W. M. Webb will be Principal Medical Officer at Netley on the retirement of Surgeon-Major-General G. L. Hinde. Surgeon-Major-General Webb's successor in Bombay will probably be Surgeon-Colonel R. Lewer.

Brigade-Surgeon-Lieutenant-Colonel C. E. Harrison, of the Brigade of Foot Guards, has been selected to act as medical representative of the British Army at the Congress on Surgery to be held in Paris, commencing on the 18th inst.

ARMY MEDICAL STAFF.—Surgeon-Major-General James Sinclair, M.D., is placed on retired pay (dated March 28th, 1892); Surgeon-Colonel Charles Henry Young Godwin is seconded for service as Professor of Clinical and Military Surgery at the Army Medical School, Netley (dated March 10th, 1892).—The undermentioned Surgeon-Majors to be Surgeon-Lieutenant-Colonels (dated March 30th, 1892):—William Donovan; Dugald Blair Brown, F.R.C.S. Edin.; Richard Henry Quill, M.B; Blennerhasset Montgomerie Blennerhassett, F.R.C.S.I.; William Budd Slaughter; Andrew Lang Browne, M.D; Christopher William Moore Keys, M.D.; and Henry Haldane Stokes, M.B. — Surgeon-Major Thos. Joseph Gallwey, M.D., is seconded for service with the Egyptian Army (dated March 25th, 1892).

YEOMANRY CAVALRY. — North Somerset: Surgeon-Captain J. J. Saville to be Surgeon-Lieutenant-Colonel (dated April 13th, 1892).

VOLUNTEER CORPS.—*Rifle:* 2nd (the Weald of Kent) Volunteer Battalion, the Buffs (East Kent Regiment): Surgeon-Major H. B. Wood, M.D., to be Surgeon-Lieutenant-Colonel; to resign his commission; to be granted permission to retain his rank, and to continue to wear the uniform of the Battalion on his retirement (dated April 13th, 1892).—2nd (Berkshire) Volunteer Battalion, the King's Own Scottish Borderers: John M'Watt, M.B, to be Surgeon-Lieutenant (dated April 13th, 1892).—2nd Volunteer Battalion the Sherwood Foresters (Derbyshire Regiment): Surgeon-Major E. M. Wrench to be Surgeon-Lieutenant-Colonel (dated April 13th, 1892).—1st (Pembrokeshire) Volunteer Battalion, the Welsh Regiment: John Henry Hywell Williams, Gent., to be Surgeon-Lieutenant (dated April 9th, 1892).

VOLUNTEER MEDICAL STAFF CORPS.—The Woolwich Division: Percy Octavius Haynes, Gent., to be Surgeon-Lieutenant, Supernumerary (dated April 9th, 1892).

ROYAL MEDICAL BENEVOLENT COLLEGE.

To the Editors of THE LANCET.

SIRS,—It gives me great pleasure to inform you that Her Majesty has been pleased to contribute £25 towards the funds of the College. The *imprimatur* of Her Majesty's approval of the efforts of the council to improve the condition of the College must surely stamp our scheme as being good.

May I not hope that such an example may induce many others to aid us, and enable us to make a securely improved position for our pensioners, and at the same time to extend and benefit our rapidly rising school? I would commend to the serious attention of your readers the idea of contributing a certain sum per annum for a term of years to this specific purpose.

I am, Sirs, yours faithfully,

April 9th, 1892. C. HOLMAN, M.D., Treasurer.

WELLINGTON COLLEGE SORE-THROAT.

To the Editors of THE LANCET.

SIRS,—Mr. Wickham is quite mistaken in supposing that I appeal to him for any opinion with respect to the nature of the three cases of sore-throat reported in THE LANCET of March 26th which occurred in his family. I pronounced them diphtheritic at the time, and treated them as such. The head master's house is so constructed that boys and others going to see the head master enter his business room or library by a side door approached by an open porch, and in that way have no necessity whatever to enter the portions of the house occupied by the head master's family. The importance of this arrangement in the event of infectious illness was fully realised by the present Archbishop of Canterbury and myself when the house was built. If, therefore, boys are exposed to infection during the occurrence of infectious illness in the head master's house, it can only be by a deviation from the usual order of things, for

WELLINGTON COLLEGE SORE THROAT.

To the Editors of THE LANCET.

SIRS,—Mr. Wickham is quite mistaken in supp I appeal to him for any opinion with respect to of the three cases of sore-throat reported in T of March 26th which occurred in his family. I them diphtheritic at the time, and treated them The head master's house is so constructed that others going to see the head master enter his or library by a side door approached by an op in that way have no necessity whatever to of the house occupied by the head master's importance of this arrangement in the event illness was fully realised by the present head Canterbury and myself when the house was therefore, boys are exposed to infection being rence of infectious illness in the head master only be by a deviation from the usual order of

which the medical officer cannot be held responsible if he is not made acquainted with it.

If Mr. Wickham doubted my diagnosis of the disease: First, why did he not mention his doubt at the time? Secondly, why did he not ask some other advice? Thirdly, why did he send for the sanitary engineer of the College to examine the drains, not only once, but a second time, till the source of the mischief was traced? Fourthly, why his great anxiety about the illness as exhibited in a letter I have, written to me at the time? But it was not only on the occasion referred to that diphtheria occurred in the head master's family. On another occasion it was diagnosed as such by another medical man who paid the first visit, acting as my deputy and on my general directions in the management of such cases. I have his note before me, from which I transcribe the following: "The eldest little Wickham has, I believe, got a diphtheritic throat, one tonsil having a large patch of that opaque-looking deposit on it. I have had her separated from the other children."

Mr. Wickham questions the nature of the illness referred to in my communication to THE LANCET of March 26th. But there can be no doubt about the gravity of the occurrence, as it impressed Mr. Wickham at the time. I have a note before me which I received from him late in the evening, from which I transcribe the following: "I asked Mr. Smith [the College architect and sanitary engineer] to come over and look at my drains, and he proposes to come by the 8.39 train to-morrow morning, and asks if you could manage to time your visit so as to meet him." In a postscript to the same note is the following: "Mrs. Wickham has had a very uncomfortable day . . . . I have not been able to get her to take more than half a tumbler of milk. You will judge if it is any use to see her again this evening." Two diseases only at that time that I am acquainted with—typhoid fever or diphtheria—could have so directed attention to the sanitary condition of Mr. Wickham's house, and typhoid fever was out of the question. Mr. Wickham knows that I, or indeed any other medical man, would do the very best for Mrs. Wickham and hers, not from a sense of duty alone, but being led thereto by her interesting character and disposition, and most angelic nature. No doubt the knotty point did arise whether the mother should continue to nurse her baby or not through her illness. The course I advised was not without precedent in my experience, and had the merit of being successful.

Sporadic diphtheria was not confined to Mr. Wickham's own family and Wellington College boys, but other persons and masters were attacked from time to time. There was difficulty in getting efficient quarantine observed. On one occasion an excellent but somewhat recalcitrant master, who chaffed at medical discipline, complained to the head master of my interference with the discharge of his duties. Mr. Wickham very properly upheld me on this occasion, and wrote as follows: "I have no doubt that you have done perfectly right in forbidding Mr. —— to go into school for another week; and I am very glad for his sake, as well as on the prudential ground of possible infection." These quotations, I think, can leave no doubt in the minds of your readers that diphtheria has in the past occurred in Mr. Wickham's house and elsewhere at Wellington College, and that due precautions were taken to guard against the spread of infection, which are the points raised by Mr. Wickham's letter in THE LANCET of April 2nd. Mr. Wickham's views respecting infectious illness at Wellington College differ materially from mine; but during the twenty-four years I attended at Wellington College the question never arose as to the dispersal of the boys, much less their withdrawal for a whole term; and I venture to think that had the medical system built up from experience during the head mastership of the present Archbishop of Canterbury been continued, the recent calamity would never have happened to the institution.

I am, Sirs, your obedient servant,
April 11th, 1892. J. G. BARFORD.

THE LONDON TEMPERANCE HOSPITAL.

To the Editors of THE LANCET.

SIRS,—I am instructed by the board of this hospital to convey to you the pain it feels on seeing a paragraph going the round of the whole medical press at home and abroad based on a statement made in THE LANCET, to the effect that ether is used in this hospital as a stimulant and as a substitute for alcohol, to which is sometimes added a reference to the danger incident to such a practice of producing a habit of ether drinking. The board directs me to emphatically and authoritatively state that no such practice is or ever has been carried on in this hospital, and that medicinally (that is, excluding its use as an anæsthetic) less ether is probably used here than in any other hospital in the United Kingdom. The board wishes me further to intimate that there is no occasion whatever for the substitution of ether for alcohol in any case, the members of our medical staff being entirely at liberty to administer alcohol medicinally if they consider such administration necessary. The statement which has gone forth is calculated to do great injury to this institution, and my board, therefore, cannot doubt that you will, in common justice, give to this letter the same publicity that was given to the paragraph of which it has such good reason to complain.—I am, Sirs, yours faithfully,
April 12th, 1892. E. WILSON TAYLOR, Secretary.

*** In THE LANCET of March 19th we inserted a letter from Dr. Ridge, in which the statement, published in the *Echo*, on which we had commented, was declared to be untrue. In an annotation in the same number of our journal we expressed the pleasure we felt in receiving and publishing Dr. Ridge's letter, and thus by implication, if not in so many words, endorsed the correction conveyed in that letter.—ED L.

THE INFLUENCE OF CLIMATE ON SURGICAL TUBERCULOSIS.

To the Editors of THE LANCET.

SIRS,—A paper recently read by Dr. Theodore Williams before the Royal Meteorological Society dealt in a very interesting and able manner with the subject of climatology in relation to the health resorts on the Riviera and in Egypt, with special reference to their suitability for consumptive cases. Important as it is to have reliable intelligence of foreign sanatoria, it is, nevertheless, to be regretted that there is a tendency to overlook the fact that these distant and expensive resorts are, after all, accessible to a very small percentage of invalids, and that the great bulk of their less wealthy brethren are compelled to remain in England and find what warmth and sunshine they may during the winter months in the few sheltered nooks on our south-west coasts.

Writers on health resorts, spas, &c., are usually physicians, and they describe the advantages these places are reputed to offer to patients with diseases of a strictly medical nature. But surgical diseases, especially surgical tuberculosis and allied disorders, have hitherto received scant attention from writers on health resorts; the surgical mind unfortunately is just now more bent on studying the natural history of microbes than on the power of the patient to resist them. It is true that the good qualities of fresh sea and country air are readily recognised in theory, but as a matter of practice a very large proportion of cases are sent out of London and other large towns only as a last resource, after the inestimably valuable weeks of early treatment have been wasted in experiments with tonics, cod-liver oil, unavailing surgical treatment, and too frequently a useless course of poulticing. Any surgeon going round our wards at the Royal Sea-bathing Infirmary for Scrofula could not fail to be struck with these facts. We get cases in all stages except the preliminary stages, when fresh air gives the surgeon and the patient a chance: pale waxen children suppurating to death through sinuses of old excisions and amputations performed in the London hospitals with every possible antiseptic precaution, patients with hopeless spinal and joint disease who have languished for months and even years in the vitiated air of city hospitals and slums. It is almost pitiable to think how many of these cases could have been benefited or saved by operation or treatment in a suitable atmosphere with plenty of light and bracing fresh air. Studded along the coasts of England there are institutions ready to relieve the great cities of cases which no surgical skill can cure in a depressing and unhealthy atmosphere.

Physicians, when they are able, do not hesitate to send their consumptive patients out of London at the first sign of the disease, and do not dally with tonics and cod-liver oil. How is it that many surgeons are so slow to grasp the importance of the climatic treatment of tuberculosis &c.? Many joints will not mend on splints alone, nor will the knife, however skilfully wielded, be successful in a large proportion of cases when the constitution of the patient is impaired by want of fresh air. If surgeons wish to follow

Digitized by Google

up their cases, a short journey to the country ought not to be too great a tax upon their time, if they consider the extra chances to their patient of an operation or other surgical treatment in a favourable atmosphere. A fairly extensive experience of unnecessarily incurable cases that have drifted even to this corner of England induces me to write strongly on the matter, and every provincial surgeon will bear me out in my statements. The records of many apparently favourable results after operation appear in the statistics of London hospitals, but we have too frequently to "complete the case.' I trust that you, Sirs, may find room for this somewhat lengthy communication, in the hope that the important fact may be emphasised afresh, that the only chance of successful treatment of a large proportion of cases of surgical tuberculosis is to move them in their earliest stage from the vitiated air of the great cities to the sunlight and fresh air of the country.

I am, Sirs, yours faithfully,

Margate, April 9th, 1892. BERTRAM THORNTON.

INFLUENZA.

To the Editors of THE LANCET.

SIRS,—In a letter which appeared in THE LANCET of Jan. 23rd, I attempted to controvert the theory that influenza attacks chiefly the centres of the medulla oblongata by hinting that the symptoms which might be expected on such a theory were conspicuous by their absence in ordinary cases of the disease. It seemed unnecessary after this to point out that the usual symptoms of influenza in no way indicate a lesion of the bulb. What are the invariable symptoms in nine-tenths of the cases of the disease? Besides febrile symptoms of a somewhat indefinite and usually mild character, there is intense pain referred to the seat of the nerve centres and various muscles, together with extreme mental and physical prostration, nothing else. Surely no greater contrast could be imagined than between such a condition and that produced by lesions of the bulb. Is it not one of the most remarkable features in glosso-labio-laryngeal palsy that a patient whose days are few to live should retain his mental and physical activity and enjoy almost perfect immunity from pain?

As one who has advocated from the first appearance of the disease in 1889 that influenza does affect chiefly the nerve centres, I am the last one to deny that in exceptional cases the vital centre of the bulb may be affected; indeed there is little doubt that the causes of many of the unexpected fatal issues of the disease are due to the failure of the vital centres. Until we have reports showing that the great majority of patients dying from influenza present some constant lesion, I shall be content to believe that, whatever the specific change caused by the disease may be, that it is beyond the present methods of pathologists to discover. In the cases quoted by Dr. Althaus it will be seen that the more general the experience the more indefinite were the lesions found, and in no instance was any special change in the medulla noted that could be looked upon as primary. I do not think I shall be alone in considering influenza to have a depressing effect upon that ultra-microscopic condition of protoplasm which, for want of a better word, and in ignorance of its nature, is usually called its nutrition. The vital centres, as a rule, resist the action of the poison, but in exceptionable cases are paralysed by it. Then the vaso-motor centre appears to be most prone to the attack of the poison, more especially that part of it that controls the pulmonary and gastric circulations. The central nervous system generally is always profoundly influenced by the poison—more, probably, in its sensory and vaso-motor than in its musculo-motor aspects. The nerve endings also seem to be much affected by the poison, and, by an increase in their irritability, tend to exaggerate the effect of the morbid condition of the nerve centres.

I am, Sirs, yours faithfully,

March, 22nd, 1892. THOS. GLOVER LYON.

SMALL-POX ON BOARD A STEAMER.—The Anglo-American Telegraph Company's steamship *Minia*, from London for Halifax, which put in at Plymouth to coal and proceeded on her voyage on Thursday last, put back to Plymouth on the 10th inst., small-pox having broken out on board. She was visited by the port sanitary surgeon, and the patients removed to the Pique floating hospital for infectious diseases. The *Minia* has a crew of eighty men.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

The Medical Defence Union.

A MEETING of the Medical Defence Union (North of England Branch) was held in the council-room of the College of Medicine, Newcastle (kindly granted for the meetings of the Union). Dr. Philipson presided, and Mr. G. E. Williamson acted as hon. sec. The principal business was the election of small local committees in each of the large towns of Northumberland, Durham, Cumberland, and Westmoreland, to act in connexion with the branch and the council in Birmingham.

Proposed Memorial to the late Dr. Heath.

An influential meeting of professional and other friends was held on Friday last, in the library of the Royal Infirmary, to promote a memorial to the late Dr. Heath. The Mayor of Newcastle presided. The attendance would have been larger but for the inconvenient hour (to most practitioners) at which the meeting was called. It was shown that Dr. Heath had been associated as lecturer at the College of Medicine, and with the Royal Infirmary as surgeon and consulting surgeon, for about forty years. It was after some discussion decided to open a subscription for the purpose of the memorial, and also that it should take the form of the endowment of a chair in the University of Durham College of Medicine, and be styled the "Heath Lectureship in Anatomy." It was shown that this would accord with one of the objects Dr. Heath had at heart—namely, the endowment of certain chairs at the College sufficient to make the holders independent of private practice, and able therefore to devote their whole time to the study and teaching of their subjects. The following subscriptions were announced before the meeting closed:—The College of Medicine (in its corporate capacity), one hundred guineas; Drs. Philipson and Gibb, each fifty guineas; and about one hundred guineas in other subscriptions. Dr. Arnison was appointed treasurer, and Lieut. Fox, R.N., of the College of Medicine, Newcastle, hon. secretary.

Alnwick.

The sewerage of Alnwick not being in a satisfactory condition, the local board proposed alterations for its improvement and disposal. Towards the estimated cost the Duke of Northumberland made an offer of £1000. As this was more than twelve months ago, it appears that his Grace is dissatisfied with the delay of the local board in a matter of this nature, and he has written through his commissioner to the board to say that if the work is not proceeded with within a month's time the offer of the £1000 will be withdrawn.

Newcastle Hospital Sunday Fund.

A meeting of the Hospital Sunday Fund Committee of Management and Distribution was recently held, and an interim cash statement as to the collections in 1891 was presented, which showed that there was brought forward from the previous year £450, the collections in places of worship amounted to £2276 16*s.* 4*d.*, manufactories £2238, special contributions £76, with interest, making a total of £5061 19*s.* 8*d.*, the collections on the whole being the largest ever received.

The late Dr. Bruce.

An esteemed citizen of Newcastle, Dr. J. C. Bruce, died here last Tuesday. Dr. Bruce was widely known as a philanthropist and a learned antiquary, but perhaps best of all, outside his own city, as the author of a history of the "Roman Wall." Indeed, it has been well said that Dr. Bruce made the Roman Wall his own, and knew every yard of it, from the Tyne to the Solway. Although not a medical man, Dr. Bruce was intimately connected with our profession as a young man. With an idea of a future missionary life, he went through, at the University of Glasgow, the curriculum of chemistry, surgery, and anatomy. Soon after, owing to the death of his father, and complying with his parent's wish, he undertook the direction of a celebrated private school in Newcastle, the well-known "Bruce's Academy," which sent forth a very large number of pupils—Robert Stephenson and others—who became distinguished in their various walks in life. Dr. Bruce held several diplomas from learned bodies so far back as 1825–6, he was a B.A., and M.A. of his own University, and in 1853 it conferred its LL.D. upon

The late Dr. Bruce.

An esteemed citizen of Newcastle, ... here last Tuesday. Dr. Bruce was ... philanthropist and a learned antiquary, ... all, outside his own city, as the author of ... "Roman Wall." Indeed, it has been ... Dr. Bruce made the Roman Wall his ... yard of it, from the Tyne to the Solway. ... medical man, Dr. Bruce was intimately ... profession as a young man. With ... missionary life, he went through, ... Glasgow, the curriculum of ... anatomy. Soon after, owing to the ... and complying with his parents' ... direction of a celebrated private ... the well-known "Bruce's Academy," ... a very large number of pupils—Robert ... others—who became distinguished ... in life. Dr. Bruce held several ... bodies so far back as 1835-6, he was ... his own University, and in 1859 it ... him. The University of Durham also conferred the same degree upon him, and he was a corresponding member or associate of a very large number of antiquarian and historical societies from Rome to America. As chairman to the governors of the Newcastle Royal Infirmary he was in constant touch with our profession, and indeed it is a question if an operator there could be more pleased with a successful result than was Dr. Bruce. It is to be feared that his zeal in the Royal Infirmary led to his death, although he was eighty-seven years of age. Sitting up at night writing its report, he allowed his fire to go out, and received a chill which led to a train of bad chest symptoms, which at his advanced age he was unable to throw off. He was attended by his own prominent pupils, Drs. Philipson and Arnison, and his remains were on Friday last followed to the grave by a concourse of citizens, including a large number of our profession; indeed, the whole city mourned his loss.

It is announced in our local papers that Professor Philipson has been nominated for the office of representative of the University of Durham in the General Medical Council.

Mr. Thomas Ironsides, the Kibblesworth centenarian, completed his 101st year yesterday (April 13th).

Newcastle-on-Tyne, April 14th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

Proposed Botanical Institute in Glasgow.

SOME weeks ago a much-respected Glasgow lady, Miss Steven, died, leaving property valued at over half a million sterling vested in the hands of a board of trustees, to whom the widest discretion is given in the use of the money, the only restriction being that it is to be devoted to "charitable and educational" purposes. Already the trustees are overwhelmed with applications for help from every kind of charitable and educational institution in and near Glasgow. One of the most recent, and probably one of the most reasonable of these, is from Professor Bower, occupant of the chair of botany in the University. He points out that, while the city has recently purchased the Botanic Gardens, which are now used as a public park, the botanical department of the University has no proper home there, but is at present lodged in two small rooms and an attic in the University building in the garden. There is no class-room, and the laboratories are so small that the practical work has to be repeated three times daily to successive relays of students. The valuable herbarium lies nursed in an inaccessible attic. Professor Bower wants a new building in the Botanic Garden, which shall be under his own control, and which shall be provided with a lecture-room to hold about 300 persons, two large museums, and a central hall, herbarium, and laboratories and private rooms for the practical work of professor and students. He has advanced his scheme so far that he has sent the trustees a sketch plan of the proposed building. The building and fittings would cost £12,500, and a similar sum would be required to give an endowment of about £400, which it is calculated would meet all necessary expenses. The total sum which he wants, therefore, is about £25,000.

Utilisation of Parochial Hospitals.

There is a proposal on foot in Glasgow to extend the reform begun about a year ago in the City Parish Hospital, when nursing by untrained women aided by convalescent patients was given up in favour of attendance of a trained staff of nurses; it is now suggested that these large hospitals should be thrown open to students and practitioners, and that the tax-supported hospitals should thus, like the charity-supported infirmaries, be made available for clinical instruction and as training fields for practitioners. It is very sensibly suggested that a hospital so large would be better worked by a staff of non-resident visiting physicians and surgeons and by resident assistants, who would perform duties in all respects analogous to those performed in our general hospitals. An immense field would thus be opened up, and clinical material at present not at all utilised would be made available for teaching purposes. The best interests both of patients and ratepayers would also be served, while the increased number of hospital appointments at the disposal of qualified practitioners could not fail to raise the general level of experience and skill in the profession. A further alteration, scarcely to be dignified by the term "reform," is proposed by Mr. Macewen, who was for nearly a quarter of a century a leading manager of the Royal Infirmary—viz., that the charge of the thirty odd wards of the Royal Infirmary should be redistributed in such a way as to give only one ward (instead of two or three) to each surgeon or physician, and that, further, the honorarium paid to the staff should be discontinued.

Hypnotism.

Dr. Kingsbury of Blackpool visited Glasgow lately and gave several very interesting demonstrations in the Royal and Western Infirmaries of what may be done by this mode of treatment. He also addressed a large and attentive audience of medical men, who on the invitation of the President, Dr. Yellowlees, met in the hall of the Faculty of Physicians and Surgeons. Dr. Kingsbury made a favourable impression as an honest and straightforward exponent of this practice, and his statements did much to rob it of the mystery in which it is often wrapped. He succeeded at the meeting in throwing a male patient suffering from neuralgia into a deep "hypnotic sleep," with no benefit apparently at the time, however, so far as pain was concerned.

April 12th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Breach of the Pharmacy (Ireland) Act in Cork.

THE recent prosecution by the Irish Pharmaceutical Society in Cork has drawn attention to the necessity which exists of having some alteration in the law by which a qualified member of the Pharmaceutical Society either of England or Ireland may use his calling in both countries at will. Mr. Selkirk has been fined £5, the magistrates expressing their regret, and suggesting that he might appeal if he so desired. There is, however, not much likelihood of this occurring, as the law bearing on the matter is distinct and definite.

Cork Poor-law Medical Association.

At a meeting of the Association, held last Saturday, reference was made to the deputation of the profession whom the Chief Secretary for Ireland refused to receive, as he did not approve of the Superannuation Bill. The chairman (Dr. D. Flynn) suggested that Sir Walter Foster should use his influence with the Chief Secretary to obtain from the Local Government Board the benefit of an annual holiday. Dr. Murphy handed in a notice of motion that at the next meeting he would move that meetings be held in remote parts of the country, in order to come in touch with some dispensary doctors who have not joined their Association as yet, and that the president and secretary attend at those meetings, the date of which would be fixed at a future period.

Cork South Infirmary.

At a meeting held on the 8th inst. the trustees of this hospital adopted the following resolution: "The resignation of Dr. W. C. Townsend having been presented to the trustees of the South Charitable Infirmary and County Hospital, in accepting it the board of trustees deeply regret the severing of Dr. Townsend's connexion with the hospital as senior physician, which he has held for so many years with great honour to himself and benefit to the patients committed to his care. We, the trustees, beg to place on record our sincere thanks to him for his constant and unsparing attention to his duties, and at the same time request that he will accept the position of consulting physician to the hospital, which the trustees have great pleasure in offering him."

Belfast Queen's College: Students' Union.

A private meeting of gentlemen in favour of the establishment of a students' union in connexion with Queen's College, Belfast, was held at the College on April 5th. The president, who has initiated the movement, stated that the want of a students' union had long been felt at the College, such as existed in Cambridge, Oxford, Edinburgh, &c., and many considered that the time had now come when a building should be erected, containing a dining-room, debating hall, recreation rooms, and also apartments where the various students' societies could hold their meetings. The jubilee of Queen's College will take place in 1895, and the president thought this would be a fitting time to open the new union. Several gentlemen at the meeting

Digitized by Google

having expressed themselves as strongly in favour of the establishment of the building, which would serve as a bond of union amongst the various students, it was decided to hold a public meeting in May, when the scheme will be formally launched. A small committee has been formed to carry out the preliminary arrangements. Mr. Thomas Sinclair, M.A., Belfast, a very distinguished graduate and warm friend of the College, has consented to act as treasurer, and already, through the praiseworthy exertions of the president, over £1100 have been promised. There can be no doubt that a students' union would be of very great advantage in many ways to those attending the College, and to none more than to the medical students. Owing to the long distances between the hospitals and the College and the city, many students are obliged to leave their lodgings early in the morning, and from that time until after five or six o'clock in the evening they are unable to dine. A students' union would obviate this difficulty, it would afford a place of rest for them between lectures, and would form a social bond of union—an element of no small value in a university.

Close of the Winter Session in Belfast.

The winter session at the hospital came to a conclusion on Saturday last, and it will terminate this week at the College. The examinations of the Royal University will begin in Dublin on April 20th and terminate on May 5th.

A series of entertainments in aid of the funds of the Dublin Orthopædic Hospital will be held in the Ancient Concert Rooms during the Easter holidays.

April 12th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

French Ophthalmological Society.

THE annual session of this Society will be inaugurated in Paris on May 2nd, when reports on the following subjects will be made by MM. Dor of Lyon, and Armaignac of Bordeaux respectively: (1) Treatment of Congenital Cataract; (2) Ophthalmoplegia.

How Quacks are punished in France.

Owing, I presume, to the sedentary nature of their occupation, shoemakers of all nationalities have from time immemorial been noted for intellectual originality, and most people can recall instances of a cobbler contravening the advice embodied in the precept enjoining him to "stick to his last." The above reflections were suggested by an incident reported in a medical journal. A worthy member of the cobbling confraternity of Havre had acquired considerable notoriety as a healer; he encountered no difficulty in imbuing the public of that flourishing port and its neighbourhood with the belief in his alleged miraculous powers. He claimed to be endowed with the faculty of prying into the secrets of the working of that part of the human economy which his patrons would probably lump together under the vague denomination "inside." To him the tegumentary and other coverings that hide these mysteries from the gaze of ordinary mortals were as transparent as glass. Not only this, but it appears that his horny hands are attracted unerringly to any part of the system that is diseased, and that such palpation remedies, *sans faute* and instantaneously, the morbid condition. These unorthodox doings having been brought to the notice of the authorities, proceedings were instituted against the ambitious worker in leather. The Tribunal Correctionel gravely deliberated over the case, two sittings being devoted to the consideration of testimony tendered by numerous individuals who had been cured offhand by this "suggestionist." If we may believe a young lady named Wolff, our eminent *confrère*, Professor Charcot, must henceforth be content to occupy a "back seat," for did not the poor shoemaker of Havre succeed in completely curing her of paralysis, whilst the celebrated neurologist of the Salpêtrière had ignominiously failed to afford her any relief? Unmoved, however, by this flattering evidence, the court decided to make an example of this unauthorised benefactor of humanity, and accordingly inflicted the tremendous penalty of—a fine of ten francs! Who shall now say that a prophet, whether he be a tinker, tailor, or cobbler, is without honour in his own country?

The so-called Parrot Epidemic.

For the last fortnight or so the lay and medical press has been publishing details of an alarming epidemic which broke out in three different centres in Paris. The disease was supposed to be a special form of epidemic pneumonia, and it was assumed to have been imported from Buenos Ayres through the medium of a cargo of parrots brought from that port by two Paris traders. Dr. Dujardin-Beaumetz has now completed his investigation of the occurrence, and he exculpates the parrots, and states that we have had to deal with a pneumonic form of influenza. The only part taken by the parrots is probably the conveyance of the germs on their plumage. Several patients have succumbed to the disease, as also many of the parrots, but the surviving parrots are in a good condition.

Paris, April 12th.

Obituary.

WM. IRVING, M.D., L R C.S.EDIN., J.P.

THE death of Dr. Irving removes from East Lancashire the oldest and most widely known physician in that district. He graduated in Edinburgh University in August, 1843. He also became a Licentiate of the College of Surgeons of Edinburgh in the same year. After a preliminary assistancy in Wolverhampton, he commenced practice at Blackburn in 1844. His attention to his patients and marked ability soon gained him a large *clientèle*, whose confidence and friendship he retained to the last. Although Dr. Irving's opinion as a consultant was sought by his professional brethren as well as by the rich and the lowly on account of his acuteness, clearness, and perspicacity in diagnosis, yet notwithstanding this and the opportunities he enjoyed as consulting physician to the Blackburn and East Lancashire Infirmary—an appointment which he held from its foundation—he left no writings behind him. Remarkably sociable, he preferred the company of his friends, the gun and the chase, as a means of relaxation rather than the quill. He was made a magistrate for the county of Lancaster on Dec. 1st, 1884. The funeral took place on Tuesday at St. Mary's, the parish church. All along the route the inhabitants showed their respect for the deceased by drawn blinds. Twenty-two private carriages joined the mournful *cortège*. It may truly be said of him that he made many friends and few enemies, and that he maintained the principle throughout life of not letting his left hand know what his right hand did.

J. W. TRIPE, M.D.

A VETERAN contemporary sanitarian has just been laid to rest in the person of the well-known Dr. Tripe. He had held the important post of health officer for Hackney for the last thirty-six years, having been the first officer to be appointed. Dr. Tripe had done excellent local work in the sanitary improvement of the large and populous area committed to him. But he was widely known outside these limits. He had filled the honourable position of President of the Society of Medical Officers of Health, and his sanitary and epidemiological writings were well known. In this latter connexion, Dr. Tripe published an interesting series of papers on epidemic waves. He also rode a tilt against the Homerton Small-pox Hospital, and his views found corroboration in the findings of the Hospitals Commission. Some later views of his as to the spread of fever from Fever Hospitals did not, however, command general acceptance. Altogether, a notable figure, whom it will be difficult to replace, has left our ranks.

THE INFIRMARY, OLDHAM.—The twentieth annual report of this charity, just issued, is a satisfactory record of the good work done during the year 1891. The experiment of providing qualified nurses to attend surgical cases outside the infirmary had worked well. 4577 patients had been treated at the infirmary in the course of the twelve months, and the convalescent homes were utilised for the benefit of thirty-seven patients. The adverse balance of £781 2*s.*, brought forward from 1890, had been reduced to £711 17*s.* 2*d.* The Hospital Saturday collection showed an increase of £154 5*s.* 11*d.* A munificent donation of £10,000 was received during the year from Mr. Eli Lees, of which £9000 had been invested in public securities. The endowment fund amounted to £31,773 1*s.* 4*d.*

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.—The following gentlemen passed the Second Examination of the Board in the subjects indicated at a meeting of the Examiners on the 7th inst.:—

Anatomy and Physiology.—Arthur H. Evans, of Westminster Hospital; Philip N. Vellacott, Thomas M. Thomas, Henry A. Moffatt, Arthur E. Philipps, Charles H. Fagge, William S. Handley, Francis J. Steward, and Richard F. Clark, of Guy's Hospital; Robert M. Le H. Cooper and Reginald J. E. Hanson, of St. Mary's Hospital; Walter E. Dixon and Harry A. Bull, of St. Thomas's Hospital; A. Woodward, George H. Sowry, and Ernest H. Fryer, of St. Bartholomew's Hospital; Frederick T. D. Clindening, of Adelaide University and St. Bartholomew's Hospital; Percy J. Edmunds, George B. Hunt, and William R. Nattle, of University College; William B. Butler and Ferdinand C. H. Muggleton, of London Hospital; William R. Coldicott, of Charing-cross Hospital.

Physiology only.—Frederick P. Duncan, of University College; Chas. Mathews and Lionel T. Wells, of St. Mary's Hospital; William H. Farmer, of St. Bartholomew's Hospital; John Gardiner, of Middlesex Hospital; William T. Dempster, of King's College; Henry N. Robson, of St. Thomas's Hospital.

Physiology only.—Stewart R. Douglas, of St. Bartholomew's Hospital.

(Seven candidates were referred in both subjects; one in Anatomy only and five in Physiology only.)

Passed on the 8th inst:—

Anatomy and Physiology.—Forbes Fraser and David B. Keown, of St. Bartholomew's Hospital; Charles M. Beadnell, Horace Pern, and Sydney G. Graham, of Guy's Hospital; Fairman R. Mann, of Middlesex Hospital; Gwilym P. W. James, of University College; Angelo Gooding, of London Hospital; Percy M. Smith and John L. Davies, of St. Mary's Hospital; Conrad C. J. Erhardt and Frank H. Jacob, of King's College; Reginald C. Gayer, of St. George's Hospital; William C. D. Hills, of Charing-cross Hospital; Sydney G. Tippett, of Westminster Hospital.

Anatomy only.—Burroughs M. Hughes and Bertram J. Collyer, of St. Bartholomew's Hospital; James Robertson, of Guy's Hospital; Frederick Moreton, of Westminster Hospital; James G. Fowler, of London Hospital; Thomas S. Farncombe, of Trinity College, Toronto, and Mr. Cooke's School of Anatomy and Physiology; Fred. W. Waters, of St. Thomas's Hospital; William A. Bernard-Smith, of King's College; G. M. Bennett and Henry C. Clark, of Middlesex Hospital.

Physiology only.—William Herbert and Howard P. Kennard, of St. Thomas's Hospital; Robert W. Jamerson, of St. Bartholomew's Hospital; John J. Winn, of London Hospital and Mr. Cooke's School of Anatomy and Physiology; C. N. Barton, of St. George's Hospital; Roderick Sim, of Middlesex Hospital.

(Two candidates were referred in both subjects; nine in Anatomy only and thirteen in Physiology only.)

Passed on the 9th inst.:—

Anatomy and Physiology.—John G. O. H. Lane, Harold B. Stoner, Charles J. Harnett, Harry M. Wise, John R. Steinbaeuser, and Daniel W. Thomas, of Guy's Hospital; James H. Hugo, Matthew W. S. Iaacke, Edward Morris, Thomas P. Legg, and J. H. Meacher, of St. Bartholomew's Hospital; Alfred P. Coker, Ernest E. Ellery, and Michael B. Pinchard, of Middlesex Hospital; Frank G. Layton and Percy W. Kent, of St. Thomas's Hospital; Dudley R. N. Bernhardt, of St. George's Hospital; R. L. Dickinson, of London Hospital; John C. Smellie, of St. Mary's Hospital; Edward L. M. Rusby, of King's College.

Anatomy only.—Charles C. Jenkins and Percy E. Tressider, of Guy's Hospital; Thos. Hood and David Lewis-Jones, of St. Bartholomew's Hospital; Edward Haines and William Ashford, of St. Thomas's Hospital; David C. Kemp, of University College.

Physiology only.—Augustus C. Greenwood, of Middlesex Hospital; John A. K. Griffith, of University College.

(Seven candidates were referred in both subjects; two in Anatomy only and seven in Physiology only.)

Passed on the 11th inst.:—

Anatomy and Physiology.—Maurice G. Pearson, Arthur Pain, John S. Stevenson, Arthur E. Druitt, and A. H. Clarke, of St. Bartholomew's Hospital; Clarence H. Mott, Frank H. White, and Joseph Cohen, of London Hospital; Ernest E. Head, of King's College; Clement E. Covernton, Bernard G. Reynolds, and Frederick S. Brereton, of Guy's Hospital; Edmund L. Perry and William H. J. Paterson, of St. Thomas's Hospital; John E. P. Davies and Sydney P. James, of St. Mary's Hospital; Charles H. J. Robinson, of Middlesex Hospital; Sidney E. Shoppee and Charles S. Read, of University College; George B. Clarke, of Charing-cross Hospital; John R. M. Forsyath, of Westminster Hospital.

Anatomy only.—Henry A. Hall, of St. Mary's Hospital; Samuel B. Blomfeld and Arthur E. Peake, of Westminster Hospital; Walter A. Sharpin and Robert C. Martin, of St. George's Hospital; William H. Pope, of St. Bartholomew's Hospital; William F. Byford, of Guy's Hospital.

Physiology only.—Arthur R. H. Skey and Thomas S. Pigg, of St. Bartholomew's Hospital.

(Six candidates were referred in both subjects; two in Anatomy only and seven in Physiology only.)

Passed on the 12th inst.:—

Anatomy and Physiology.—George Phillips, Arthur Hunnard, J. Coote Hilbert, William Roberts, and Robert M. Johnston, of University College; Cecil A. Ensor, Edward T. Scowby, and Benjamin A. Richmond, of Guy's Hospital; Charles R. Watson, Frank Morley, Robert M. Ellis, and Boghas B. Tahmisian, of St. George's Hospital; Francis S. Tidcombe, of St. George's Hospital and Mr. Cooke's School of Anatomy and Physiology; George F. S. Genge and Henry Morris, of Westminster Hospital; Joseph E. G. Calverley, Arthur W. R. Cochrane, Frank M. Burnett, John F. Bill, and Arthur H. Morris, of St. Bartholomew's Hospital; William D. Frazer and Robert G. Strange, of St. Thomas's Hospital; Arthur P. Gibbons and Cyril B. Howse, of London Hospital.

Anatomy only.—Edward G. Moon, of St. Mary's Hospital; William A. Carden, of Guy's Hospital; Montagu H. C. Palmer, of London Hospital; Arthur A. Rogers, of St. Bartholomew's Hospital.

(Eight candidates were referred in both subjects, and four in Physiology only.)

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentleman, having previously passed the necessary examinations, and having now attained the legal age (twenty-five years), was, at the ordinary meeting of the Council on the 7th inst., admitted a Fellow of the College:—

Paton, Edward Percy, M.B. Lond., L.R.C.P. Lond., St. Bartholomew's Hospital; diploma of Member dated Aug. 1st, 1889.

CAMBRIDGE UNIVERSITY.—The following candidates have satisfied the Examiners in both parts of the recent examination in Sanitary Science:—

Bamber, C. J.	Jones, J. H.
Davison, T. H.	Roe, W. A. C.
Elliot, R. H.	Semple, D.
Fligg, W.	Taylor, J. M.
Foster, W.	Taylor, M. H.
Hadley, W. J.	Thresh, J. C.
Hodges, W.	Trevor, E. T.
Hyatt, J. T.	Weir, G. W.
Jones, A. L.	

UNIVERSITY OF GLASGOW.—The following gentlemen have passed the Third Professional Examination for the degree of M.B. and C.M.:—

A, including Pathology.—William Cassels, James Cochrane, Peter Forrest Dewar, George Edgar, Alfred Forrest, M.A., Andrew Graham, Ernst Denny Scott Heyliger, William Munn Hunter, Neil Keith, Robert M'Farlane Marshall, James Robert M'Cheyne Miller, M.A., William M'Gall, George Nicoll, Peter Rankin, James Bryce Robertson, John Davidson Smith, John Barr Stevens, James Thomson, Peter Thomson, Henry William Williams, James Murray Young.

B, not including Pathology.—Thomas Barrowman, Duncan Francis Brown, Allan Cameron, Vivian Ernest Chang, Thomas Colvin, William Copland, George Alexander Eadie, Edward Arthur Eckersley, John James Fraser, Thomas Adams Stewart Gibb, Alfred Alex. Cumming Grant, David Fraser Harris, B.Sc., William Irwin, James Ritchie Jeffrey, Alexander Kelso, David Millar King, Robert Langmuir, M.A., Thomas Burns Marshall, James Binnie Millar, John Munro, Duncan MacDonald, James M'Kee, James Morton MacLauchlan, Balfour Stewart Nicholson, John Paxton, Alfred Fred. Septimus Pearcey, Peter Patton Petrie, M.A., Allan Ramsay, Hugh Robertson, John Selkirk, M.A., William Northcote Sime, Johnson Marion Smith, Nathaniel Stevenson, M.A., John Provand Thomson, David Wallace, Alfred Webster, Alexander Grieve Young.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS IN IRELAND: CONJOINT SCHEME.—The following have passed the First Professional Examination:—

M. Carraher, M. J. Carroll, C. J. Cavenagh, M. Corry, H. E. Deakin, G. H. Fisher, P. J. Fitzsimons, H. Herrick, J. R. Hewitson, E. C. Hodgson, E. J. Hogan, M. Hurley, D. Jones, W. Lawler, E. J. Lynch, M. R. Moore, J. McCarthy, B. McCaul, J. A. Neary, D. O'Brien, J. Thomson, and F. Wise.

SOCIETY OF APOTHECARIES OF LONDON.—The following candidates have passed the recent primary examination in the respective subjects:—

Part I.

Chemistry, Materia Medica, Botany, and Pharmacy.—W. S. Robinson, Queen's College, Birmingham; L. M. Yardley, Royal Free Hospital.

Chemistry.—F. T. Knott, Guy's Hospital; E. Wright, Queen's College, Birmingham.

Materia Medica, Botany, and Pharmacy.—H. E. Davis, St. Thomas's Hospital; E. C. B. Ibotson, Guy's Hospital.

Pharmacy.—E. H. Forgett, Edinburgh University; L. Macrae, King's College and Glasgow; W. Taylor, Queen's College, Birmingham.

Part II.

Anatomy and Physiology.—C. J. Barnes, King's College; A. D. Clark, St. Bartholomew's Hospital; J. L. Davis and S. J. Haylock, St. Mary's Hospital; K. M. Hunter, Royal Free Hospital; E. C. B. Ibotson, Guy's Hospital; R. W. Middleton, Yorkshire College, Leeds; E. G. Moon, St. Mary's Hospital; R. A. McW. Robinson, Belfast; J. J. Speais, London Hospital; P. R. Wallis, University College.

Anatomy.—W. E. V. Gould, Queen's College, Birmingham; T. Gregg, St. Bartholomew's Hospital; J. B. Hodgson, Manchester and Glasgow; J. E. Jones, London Hospital; L. J. K. Lake, King's College; B. H. Leigh, Owens College; S. E. H. Martin, Royal Free Hospital; T. J. M'Culla, London Hospital; A. P. Square, Middlesex Hospital; J. R. D. St. Cyr, St. Bartholomew's Hospital; J. H. E. Trout, Queen's College, Birmingham; J. J. Winn, London Hospital.

Physiology.—J. T. Brickwell, Guy's Hospital; A. H. Bygott, Queen's College, Birmingham; H. Clapham, Sheffield; R. N. De Beauvais, Aberdeen; A. E. Freer, St. Mary's Hospital; A. R. McCullagh, Charing-cross Hospital; W. E. Pain, Guy's Hospital; C. J. Underwood, Charing-cross and London Hospitals; A. Wheeler, Edinburgh.

THE yellow fever in Brazil is reported to be further spreading from the Brazilian coast to the interior. The principal victims are said to be Germans, English, Swiss, Austrians, and Swedes.

INFLUENZA AMONGST HORSES.—A serious epidemic of influenza is reported to exist amongst horses in London. It is stated that the outbreak is more virulent than any which have preceded it.

HOMES FOR WORKING BOYS IN LONDON.—The Princess Christian has consented to lay the memorial stone of a new City Home for Working Boys on June 15th, attended by the Lord Mayor. The home has been carried on at 30, Spital-square for twenty-one years, doing a most useful work amongst lads engaged in the City. The building and freehold will cost £9500, towards which £3200 has been subscribed by the committee and a few friends. The home is one of eight known as Homes for Working Boys in London. The Hon. T. H. W. Pelham is treasurer, and the office is at 18, Buckingham-street, Strand, W.C.

THE GENERAL PRACTITIONERS' ALLIANCE.—A general meeting of the members of the above Society was held at Exeter Hall on Tuesday, April 5th, George Brown, M.R.C.S. (President), in the chair, to consider the proposed Royal Charter to the Royal British Nurses' Association. The following resolution was proposed by Dr. G. J. Eady, seconded by Dr. F. H. Alderson, and carried unanimously:—"That this meeting of the General Practitioners' Alliance considers that the registration of trained nurses is a measure which is calculated to protect the sick against untrustworthy nurses, and will be of much advantage to medical men by affording them ready and reliable information as to the training and experience which nurses have received. This meeting, therefore, believes that it would be for the public welfare that the Royal British Nurses' Association should be incorporated by Royal Charter, and requests the president of the Alliance to forward a copy of this resolution to the Lord President of the Privy Council."

BEQUESTS AND DONATIONS TO HOSPITALS.—The late Major Barker of Wakefield bequeathed £2000 to the Clayton Hospital, Wakefield, £1000 to the Albert Asylum, Lancaster, £200 to the Scarborough Sea-bathing Hospital, and £100 to the Lock Hospital, London. Miss Louisa H. F. Bennett, late of Florence, bequeathed £6000 to the Manchester Royal Infirmary, £1000 each to the Middlesex Hospital and St. Thomas's Hospital, London, £3000 to the Hospital for Consumption, Brompton, £2000 to the Cancer Hospital, Brompton, and £5000 to the British Home for Incurables, for the purpose of founding a ward to be called the "Hannah Fawsett Bennett" Ward. The late Mr. Oliver Heywood of Manchester bequeathed £5000 to the Children's Hospital, Pendlebury, £3000 to the Salford Royal Hospital and Dispensary, and £2000 to the Manchester Infirmary. The treasurer of the Salford Royal Hospital has received a legacy of £500 from the executors of the late Mr. J. Hampson of Kempsford. The Goldsmiths' Livery Company has made grants of £250 and £500 to the Westminster Hospital and the Middlesex Hospital respectively. The following bequests have become payable by the death of Dr. George Miller of Glasgow:—£300 each to the Royal Infirmary and Western Infirmary, £200 to the Victoria Infirmary, £100 to the Royal Hospital for Sick Children, and £200 to the Colquhoun Bequest Fund for Incurables—all of Glasgow. The late Mr. William Blanchard of New Hampton bequeathed £500 each to the Richmond Hospital and the Teddington Hospital, £200 each to the Dispensary, King-street, St. James's, and the French Hospital, £100 each to the Hospital for Diseases of the Throat, Golden-square, to the Hospital for Diseases of the Skin, Leicester-square, to the Hospital for Consumption, Brompton, and to the Convalescent Home, Weybridge. Mr. George C. Ash, late of Maida Vale, bequeathed £500 each to the St. Mary's Hospital, Paddington, Middlesex Hospital, Charing-cross Hospital, University College Hospital, London Fever Hospital, King's College Hospital, Royal Free Hospital, London Hospital, Westminster Hospital, and the Hospital for Consumption, Brompton. The late Mr. Chas. H. Wagner of Birmingham bequeathed £500 each to the Birmingham and General Hospital and the Queen's Hospital, Birmingham, £300 to the Birmingham General Dispensary, £100 to the Children's Hospital, Birmingham, and £50 to the German Hospital, London.

SMALL-POX IN DORSET.—Small-pox, which broke out last week at the Union Workhouse at Shaftesbury, is reported to be spreading, notwithstanding the most stringent precautions.

MEDICAL MAGISTRATE.—The name of George Henry Browne, L.R.C.P.Edin., L.F.P.S.Glas., has been placed on the Commission of the Peace for the county of Brecon.

HOSPITAL SUNDAY FUND.—The late Dr. H. Elthington Price, of No. 1, Tisbury-road, West Brighton, left a legacy of £105, free of duty, to the Hospital Sunday Fund.

NAVAL MEDICAL SUPPLEMENTAL FUND.—At the quarterly meeting of the directors of the fund, held on the 12th instant, T. Russel Pickthorn, Esq., Inspector-General, in the chair, the sum of £80 was distributed among the several applicants.

TWO Tartars in the neighbourhood of Kazan have been sentenced to twelve years' penal servitude for the murder of a little girl of six years of age. They had cut out her heart to give it to a sick person to eat, as a human heart had been prescribed by a mullah!

COUNTY COURT ACTION AND COUNTER ACTION.—Messrs. Mason and Smith, surgeons, in the St. Austell's County Court, brought an action against Mr. Alfred Warne, and were met by a counter-claim for negligence and unskilful surgery and damages for £50, their claim being for £7 12s. 6d. Fortunately, the defendant had a sensible solicitor, who saw that there was no evidence in favour of the counter-claim and withdrew it. His lordship gave a verdict for the plaintiffs, with costs.

THE QUEEN AT HYÈRES.—In recognition of the interest manifested by the members of the British colony in the Infant Asylum at Hyères, the committee of the institution have solicited from the Queen permission to designate the bed last established by the name of some member of the Royal family. The Queen, in reply to this petition, has remitted a sum of money sufficient to instal four additional beds in the hospital, signifying at the same time her wish that they should respectively bear the names of Queen Victoria, Princess Beatrice, Duchess of Connaught, and Princess Margaret Victoria of Connaught.

MEDICAL NOTES IN PARLIAMENT.

Small-pox in London.

IN the House of Commons on Monday last Mr. Ritchie, replying to Mr. Talbot, said: I have been strongly impressed with the great importance of the local authorities taking the most energetic measures with the view of preventing the spread of infection when these cases occur, and in May last I wrote to the vestry of the parish of Shoreditch and to the several other vestries in the metropolis asking them specially to instruct their medical officer of health in every case of small-pox which might be notified to him, or which might come to his knowledge, immediately to visit the house where the disease had broken out, and at the earliest possible moment to take such measures as might be necessary to secure as far as practicable the isolation of the patient, the vaccination of any persons who might have been exposed to infection, and the disinfection of the premises, and any further action which the circumstances admitted of for the purpose of checking the extension of the disease. I am informed that the medical officer of health reported to the vaccination officer the outbreak of small-pox in the two houses referred to, and that the vaccination officer immediately visited the inmates and urged them to obtain vaccination and revaccination. Unfortunately his warning appears to have been disregarded. I learn that an arrangement has been made for vaccination daily of urgent cases by one of the public vaccinators of the parish. With respect to revaccination, there is no law under which this can be enforced. As regards vaccination, I am strongly impressed with the responsibility of parents who neglect to have their children vaccinated, and of the local authorities who fail to put in operation the law as to the enforcement of vaccination, especially where an outbreak of small-pox has actually occurred.

Burgh Police and Health (Scotland) Bill.

The House went into Committee on this Bill. On the first clause, Dr. Clark moved to report progress, as no opportunity had been afforded for putting down amendments. He afterwards withdrew his motion, and the Bill was proceeded with.—On the motion of Dr. Cameron progress was reported, when Clause 340 was reached on the ground that succeeding clauses opened up debateable matters relating to public health and borrowing and rating powers.—The motion was agreed to.

Midwives' Registration.

On the motion of Mr. Fell Pease, the Select Committee on Midwives' Registration was nominated as follows: Mr. Bright, Mr. Tatton Egerton, Dr. Farquharson, Sir W. Fitz Wygram, Dr. Fox, Mr. Howorth, Sir Guyer Hunter, Mr. Fell Pease, Mr. Rathbone, Mr. Stephens, and Mr. Arthur Williams; five to be the quorum.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

We cannot undertake to return MSS. not used.

COSTLY LIBEL OF A MEDICAL MAN BY A VENDOR OF PATENT MEDICINES.

MR. ALFRED ELLIS VAUGHAN of Haslington has set an excellent example of the right way of rebuking an impudent libel by a "quack." He had a club patient named Cooke with an abrasion of the finger. Cooke was anxious about his finger, and Mr. Vaughan promised to call in another practitioner. Thereupon Cooke went to Samuel Johnson, a vendor of quack medicines, who, according to the report of the trial for libel at the Chester Assizes, gave Cooke "a lotion which was neither good nor bad." The libel was contained in a testimonial published by Johnson, and purporting to have been written by Cooke. It set out that Cooke had been unsuccessfully treated, and added, "I must have died in two more days had not my friends advised me to escape and come to you at once. I did so." Mr. Johnson's powers are further set off in extracts from his pamphlet. "I cure the worst fever in three days certain, the worst inflammation in six hours certain, twist of the bowels in six hours certain," &c. It may be hoped that this benefactor of his race may have got a "twist" in the direction of greater honesty by the fine imposed for his libel on Mr. Vaughan in the form of damages £250.

W. H. M.—We doubt very much if the solicitor, who is merely agent of the client, is liable. The client certainly is responsible to our correspondent for his fees.

W. E. G.—It is a legal question. But we think, in the circumstances stated, B. ought to pay the balance.

EPISTAXIS.

To the Editors of THE LANCET.

SIRS,—In your issue of Feb. 6th of this year was a very excellent article by Dr. A. A. Philip on "Epistaxis: an Easy and Effectual Method of Plugging." The method he describes struck me as at once simple and much preferable to the ordinary mode of using Bellocq's cannula, inasmuch as it is quicker and easier to perform. I have lately had a case of epistaxis which resisted ordinary methods of treatment—viz., compressing the upper lip, application of ice externally and internally, syringing with tincture of hamamelis and cold water, syringing with hot water. I then resorted to Dr. Philip's method, using a piece of oiled silk, with the result that the bleeding stopped at once. The following day I removed the plug without the least difficulty or discomfort to the patient, and the bleeding has not returned since. I feel very grateful to Dr. Philip for his valuable suggestion.

I am, Sirs, yours very truly,

Bath, April, 1892. OTTO HOLST.

DEATH UNDER BROMIDE OF ETHYL.

DR. GLEICH reports a fatal result from the use of this anæsthetic. It occurred in Professor Billroth's clinique in March last, the patient being a man of forty-eight years of age, in hospital for extensive furunculus of the right arm. Before making the incision the operator had him anæsthetised with bromide of ethyl, but two minutes had barely elapsed when cyanosis appeared and pulse and breathing stopped. Artificial respiration was practised for an hour and a half, but without the slightest effect. At the necropsy there was found degeneration of the myocardium and of the liver; the renal epithelium, moreover, was undergoing degenerative change. There was, however, little or nothing of the hyperæmia, which is an almost invariable phenomenon in death under chloroform. It seems difficult to tax the bromide of ethyl with the fatal result. In conditions similar to those of the patient in question no other narcotic could have been employed without imminent risk.

Mr. P. J. Thomson.—1. Dr. Radcliffe Crocker's book, "Diseases of the Skin," published by Mr. H. K. Lewis.—2. The best English Atlas at present is that of the New Sydenham Society, but it is as yet incomplete. Professor Neumann has lately published one in Vienna. We believe Mr. Y. J. Pentland is about to issue an atlas, to commence some time in the autumn of the present year.

Perplexed.—Our correspondent was not treated fairly or summoned formally. A medical man is only bound to attend when he receives a formal summons signed by the coroner. We should not advise him to do more than complain of the informality of the summons and the shortness of the notice.

MICROSCOPICAL WORK.

To the Editors of THE LANCET.

SIRS,—No doubt there are many men like myself working at the micro cope, and endeavouring to keep our bacteriological knowledge up to date. The discussion at the Pathological Society on Phagocytosis furnished the most interesting series of papers that have been published for a long time. Now a great requisition is a gentleman who would undertake to examine any microscopical specimen sent "carriage paid" to him, with stamps to defray the cost of its return. No one would wish to occupy his time or for him to do it gratuitously, and if the necessary fees were not remitted, let him disregard the application. It would often be a great satisfaction to get a good microscopist to verify one's nomenclature, or say—"You have made a mistake; it is so-and-so; prepare the next specimen according to direction." I hope I am making a good suggestion; for I feel there is a great desideratum for such a gentleman, if he will come forward and volunteer his services. It would give an impetus to pathology and bacteriology throughout the country. I am, Sirs, yours faithfully,

April 11th, 1892. M.R.C.S.

THE DECIMAL SYSTEM.

THE New Decimal Association has just issued its second report, which gives a record of satisfactory progress in the work it has undertaken. The metric system is, as is well known, in use in Germany, France, Italy, Holland, Spain, Portugal, and many other countries, and it can, we think, be only a question of time for its manifold advantages to be practically recognised by all the nations of the world.

Omega, L.A.H., &c.—The treatment is at best unsatisfactory. Abstinence from alcoholic liquors should be strongly insisted on, and the bowels carefully regulated with saline purgatives and an occasional mercurial pill. Iodide of potassium would also probably prove useful. Should ascites occur, the fluid should be drawn off. But no single treatment can be suggested; such must necessarily be expectant.

Mr. Piggott (Clare).—Very shortly.

"PTYALISM."

To the Editors of THE LANCET.

SIRS,—I would advise "M.B., C.M." to give his patient chlorate of potassium in solution, in the proportion of an ounce to a pint of water—an ounce of the solution thrice daily before food. I published my experience of the remedy in cases of ptyalism and dry-mouth in the *Dublin Journal of Medical Science*, August, 1880. The medicine acts as a regulator in functional derangement of all conglomerate glands: in the case of ptyalism by reducing to normal limits the secreting power of the gland, and in cases of dry-mouth by exalting the physiological action when below par.—I am, Sirs, yours faithfully,

Belfast, April, 1892. ALEXANDER HARKIN, M.D., F.R.C.S.

To the Editors of THE LANCET.

SIRS,—Must we not consider the case given by your correspondent as one of chronic catarrh, similar to lachrymal catarrh or nasal catarrh, so frequently seen in old people? I have found the latter in connexion with a general weakness of circulation of the blood, and much improvement to result from a course of heart tonics, especially nux vomica.

I am, Sirs, yours faithfully,

April, 1892. M.R.C.S.

"POISONOUS CIGARETTES."

WE have received from various cigarette manufacturers samples of cigarettes the innocuousness of which does not appear to be suspected. If an opinion as to quality is required, they should be submitted of course to an analyst; but if there is reason to suppose that the practice of employing arsenic or other injurious materials in their manufacture is resorted to, then we should feel it our duty, in the interest of public health, to give the matter our serious attention. We have also received from one firm an interesting letter in which the writer is of opinion that harm frequently results from the use of uaripe tobacco, or of tobacco containing an undue proportion of isaluc, and from the ingredients used as flavouring agents, as well as from the practice of inhaling the smoke resorted to by some smokers. With the substance of these remarks we quite agree.

Dr. Edward Little.—"Natural premiums" (so-called) are calculated to increase with the age of the policy, and therefore to become very burdensome in course of time. This does not matter if a temporary assurance is all that is wanted; but that can be obtained more cheaply with the old-established offices than with these new comers in the insurance field. Comparisons such as are commonly made between "natural premium" policies and ordinary policies are apt to be very misleading, because the gradual growth and eventual burden of the natural premium are apt to be ignored and overlooked. Hence these schemes cannot be recommended in an ordinary case—the risks of present misunderstanding and subsequent disappointment are so great. Further than this, their best terms can always be bettered by the old companies. See the new Premium Table just issued by the London Life Association.

C.—It would not be in good taste. The professions are not to be confounded in one person.

SPRAY PRODUCERS WITH CHECK ACTION.

To the Editors of THE LANCET.

SIRS,—In your issue of April 9th, under the heading of "New Inventions," is an illustrated account of a "new" spray producer with check action, for applying medicaments to the larynx &c. I received from Berlin in the latter part of 1889 a similar instrument attached to a test-tube with foot-piece. Messrs. Weiss of Oxford-street in that year; at my suggestion, modified this instrument for me, the modification consisting of a screw arrangement, by which it can be attached to the neck of any bottle. They also at the same time made me a foot bellows to use with the above. This was in 1889; so I hardly think it can now be called a "new invention." I shall be much obliged if you will insert this in your next issue in justice to Messrs. Weiss, who were, I believe, the first makers of this ingenious device in London.

I am, Sirs, yours faithfully,

Devonshire-street, W., April 11th, 1892. W. R. H. STEWART.

*** Messrs. Weiss and Son send us a letter to the same effect as the above.—ED. L.

PUFFING OF MEDICAL MEN BY THE LAY PRESS.

WE extract the following from the *St. John's Wood, Kilburn, and Hampstead Advertiser*. Dr. Gaster is to be pitied for such an unseemly newspaper puff.

> "Dr. A. Gaster has removed from 31, Warwick-road, Maida-hill, to 100, Abbey-road. This young rising physician was pupil of the famous professor, Dr. Babes, discoverer of the microbe of influenza, which has wrought such ravages in our midst of late. Dr. Gaster has contributed many original articles to different medical journals abroad, where he has taken his degree of M.D. with special honours, and subsequently passed as member of the Royal College of Physicians, London. He has held the appointment of house physician, house surgeon, and resident medical officer abroad; and house physician to the City of London Hospital. Dr. Gaster is the son of Chevalier A. E. Gaster, secretary to the Dutch Legation, and brother to the well-known Rev. Dr. Gaster, of Warwick-road, W."

Inquirer.—No qualification is required, but it must be borne in mind that all the responsibility lies with the principal.

CREMATION.

CREMATION is growing in popularity among the French. Last year 3741 bodies were cremated, and the second crematorium in the Père Lachaise cemetery had to be enlarged. Italy has twenty-two crematoria, among them several perambulating ones. In Germany three new ones were opened in 1891. In other countries also the practice is becoming popular.

R. P. W. will find the information in our Students' Number, published in September last.

Dr. A. H. Smith (New York).—The paper will appear in an early number.

THE PERILS OF DEATH CERTIFICATION IN SPAIN.

FROM a case which has just been published in *La Independencia Médica* it would appear that a Spanish medical man practising in Tarragona was sent for to a poor cottage some two hours distant, to see a man who said he had had a chill, with pain in the side and headache, and who seemed so weak that he could not raise himself in bed. The temperature and pulse were normal, and nothing was discovered by auscultation and percussion. The tongue was dry and dark. The patient seemed very despondent about himself, though the doctor did his best to reassure him by telling him that there was no cause for anxiety. In the evening the wife called on the doctor, telling him that her husband had become worse, and begging that he might be visited as early as possible next day. The doctor was surprised at this intelligence, and was still more astonished when, just as he was starting to pay the required visit the next morning, a messenger arrived, saying that the man was dead. The only conclusion he could come to was that some unsuspected complication had arisen which had rapidly carried the patient off; and when he was asked to fill up the death certificate later in the day he mentioned to the person who came for it his surprise at the patient's death. It was ultimately discovered that the whole case was an attempt to defraud an assurance company of 40,000 francs, the coffin when it was exhumed containing only a bag of earth and some fæces, which were employed for the purpose of preventing the neighbours from viewing the body, which was said to have burst and to be most offensive. The guilty parties were punished, and the doctor, who was found by the court to have given a false certificate "with rash imprudence," was fined 125 francs, and was ordered to pay costs amounting to a much larger sum. Fortunately for him, the assurance company testified its gratitude for the very important aid he had given it in resisting the claim by indemnifying him from all pecuniary loss. In the absence of any evidence as to the details of the cause of death given in the certificate we can hardly express an opinion as to whether the medical practitioner was deserving of sympathy. We are inclined to think that, under such circumstances as those narrated above, an English medical man would undoubtedly refuse to certify

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

COMMUNICATIONS, LETTERS, &c., have been received from—Messrs. Allen and Hanburys, London; Dr. Anningson, Cambridge; Mr. Appleyard, Bradford; Commander Blount, R.N., Chelsea; Messrs. THE IDEAL NUTRITIVE BEVERAGE.

ESSENTIA MALTI (KEPLER).

WE have recently introduced a new food agent and aid to the digestion of farinaceous substances under the above name. This preparation is manufactured by a modification of the KEPLER process for making the well-known **Kepler Extract of Malt.**

The KEPLER ESSENCE OF MALT contains a large amount of **Diastase** and natural mineral phosphates, and a considerable amount of tissue-forming substances. *The immense superiority of this preparation over ale and stout* is at once apparent when the process of manufacture is considered in detail. In making ale and stout the carbo-hydrates (so valuable as nutrient material) and the diastase (a most important principle of Malt, being of special service in errors of nutrition accompanied by digestive derangement) are sacrificed for the production of alcohol; whereas *in the KEPLER ESSENCE OF MALT these are carefully preserved intact.* This Essence is therefore an ideal aid to digestion and nutrient agent. **A wine-glassful of the Kepler Essence of Malt contains more elements of nutrition than a pint of the finest alimental stout.**

The flavour of the ESSENCE OF MALT is delicious. It is admirable as a table beverage when diluted with aërated water, and as an addition to milk for infant and invalid dieting; for it sweetens it and facilitates its prompt and perfect digestion. The Essence may be taken in coffee, gruel, aërated or plain water, wine, or mixed with any farinaceous pudding. As an addition to the food for young children its value cannot be over-estimated. It increases the value of all farinaceous food, and prevents the starch in such food, and large clots of curd in milk diet, overtaxing the power of the digestive functions.

For Lactating Women the ESSENCE OF MALT (KEPLER) contains many desirable properties; it quickly increases the flow and enriches the quality of the milk. It is serviceable as a laxative for young children, especially when constipation depends upon the defective digestion of starch. As a food beverage, it cannot fail to be productive of the highest benefit, either in **acute disease** or during **convalescence**; in fact, wherever there is defective nutrition, the KEPLER ESSENCE OF MALT is useful as a nutritive food.

As a Linctus, the Essence of Malt food, swallowed slowly, affords marked relief in the troublesome, dry, laryngeal cough, and the hacking cough of puberty or consumption, is pleasantly grateful and soothing, aids digestion, and builds up the tissues.

The KEPLER ESSENCE OF MALT is supplied to the profession in champagne pints at 1s. 2d. each. Retail 1s. 6d. each.

BURROUGHS, WELLCOME, & CO., SNOW HILL BUILDINGS, LONDON, E.C.

A Specimen will be sent free to any Medical Man on request.

SPECIAL ADVANTAGES OF

BYNO-HYPOPHOSPHITES

AS A GENERAL TONIC.

Composition.—BYNO-HYPOPHOSPHITES consists of a neutral solution of the *Hypophosphites of Iron, Manganese, Calcium,* and *Potassium,* to which are added the *alkaloids of Cinchona* and *Nux Vomica,* the whole being in combination with *Bynin,* our Liquid Extract of Malt, already well known to the profession. There are two points about the mixture which are especially noteworthy:—

1. The alkaloids are present as they are found in the plants from which they are derived—that is, in combination with the natural acids,—and in this condition are believed to be more readily assimilable. The quantity of each present is accurately measured—there being, e.g., 1-40 grain of Strychnine to each ounce of the mixture.
2. Since sugar, as used in ordinary Syrups of Hypophosphites, is liable to cause dyspepsia or other troubles, it is here replaced by the valuable nutrient and digestive constituents of Bynin.

General Properties.—BYNO-HYPOPHOSPHITES is an amber-coloured clear liquid, readily miscible with water, of agreeable, very faintly bitter taste, deposits no sediment, and leaves no persistent taste in the mouth.

Therapeutics.—Whether or no Hypophosphites enable Phosphorus to be administered in a more readily assimilable form than do other combinations of this drug, it is as certain as extended clinical experience can make it that a combination of metallic Hypophosphites is of great value in Bronchitis, Phthisis, and other respiratory disorders, having a powerful stimulating effect, acting on the nervous system especially. The advantages to be derived from the general tonic action of the alkaloids of Cinchona and Nux Vomica and the digestive and nutritive properties of Bynin are obvious.

Dosage.—BYNO-HYPOPHOSPHITES should be given immediately after a meal, or may be taken in water with the meal. The dose is a dessert-spoonful to a tablespoonful, which may be gradually increased up to two tablespoonfuls, three times a day.

The British Medical Journal writes:—"The preparation has an agreeable taste, and is very easily miscible with water, forming a perfectly transparent solution."

The Hospital Gazette writes:—"The value of such a preparation in cases of wasting diseases, debility, and nervous prostration, especially when associated with impaired digestion, must be obvious, as, in addition to the tonic action of the hypophosphites and alkaloids, digestion of food is promoted by the diastase contained in the malt extract, which in itself is a highly nutrient agent."

Sold in Bottles at (Retail) 2s. 6d. and 4s. 6d.

Lumleian Lectures

ON

CERTAIN POINTS IN THE ETIOLOGY OF DISEASE.

Delivered at the Royal College of Physicians on March 31st and April 5th and 7th, 1892,

BY P. H. PYE-SMITH, M.D., F.R.S.

LECTURE II.

MR. PRESIDENT AND GENTLEMEN,—In my first lecture I endeavoured to open the statement that we are wrong if we seek for the cause of disease as of some monstrous and abnormal—almost illegal—interruption of our comforts and our life; that diseases are part of the vast and mysterious, though beneficent, system under which we live, that morbid processes are strictly physiological, and that the origin and conditions of diseases and of death must be sought by the same methods as the origin and conditions of health and of life. I would deal with etiology as a branch of natural history—and Historia, let us remember, signified inquiry as well as record,—to be studied in the light of comparative pathology and the great principle of evolution. I sought to direct attention from this point of view to the meaning of parasitic diseases, of injuries and irritants, of contagion, of diathetic states, congenital lesions and degeneration, and referred to the operation of such general biological laws as reaction to stimuli, habit, tolerance and immunity, heredity and degeneration.

We now come to the second division of our subject—the general etiological conditions which cause or favour diseases, not as accidents, injuries, degeneration and decay which affect individuals, but as predisposing rather than exciting causes, affecting groups of mankind, according to sex, age, and occupation, the climate they dwell in, and the race to which they belong.

Statistics.—Here we have less guidance from direct observation of cases and none at all from experiment. The conditions in question are too complex, and we have to depend almost entirely upon the method of statistics—i.e., the collocation in large numbers of instances. Here, if we would walk surely, we must walk warily, for the pitfalls are many.

Let me offer a few examples. It was said by a biographer of the great Dr Thomas Young, that although his scientific achievements far exceeded his work in his profession, yet that it was a remarkable fact that the percentage of deaths among his patients at St. George's Hospital was far lower than among those of his colleagues: doubtless the explanation was that fewer acute and interesting cases were admitted to his wards than to those who were more zealous in their calling. By the returns of the Lying-in Charity of Guy's Hospital, extending over several years, it was conclusively proved that more women were brought to bed of their second child than of their first: the inexperienced primipara did not often seek the skilled assistance which she afterwards took care to secure. If any disease is found to be as frequent in elderly people as in children, it is clear that they are not equally, but far more, liable to it, since many children do not reach old age, but every old man or woman has been a child: quite apart from incidence on one age or another, the cases of death from any disease will be less frequent late in life than early, because there are fewer to be ill of it. The superiority of the treatment of enteric fever by cold baths was once asserted on the strength of the very low mortality among patients so treated in the military hospital, Munich: but it was forgotten that with picked men of a very favourable age, free from chronic disease, well-fed and housed and nursed, any treatment would be likely to show better results than in cases taken from the population at large. Again, more male than female children come into the world; hence, for the first few years of life the proportion of deaths of boys from any indifferent accident or disease will be greater than that of girls, other things being equal: the disproportion is gradually redressed, and after fifty the number of women dying from any given disease, with no special sexual incidence, will, other things being equal, be greater than that of men.

Statistics, to be of value, must be taken without selection, designed or unintentional; they must refer to the same things—in etiological inquiries to well-defined and easily recognised diseases; they must be in sufficient number to compensate for such accidents as a "run of heads" before a "tail" appears; and they must be carefully "corrected" by such other statistics as the number of persons available for each enumeration.[1]

Etiological relations of sex.—With respect to the influence of sex in the causation of disease many interesting facts show the wide-reaching difference in physiology between men and women, exclusive of diseases directly and obviously connected with the uterus and ovaries, with menstruation, pregnancy, and lactation. (1) Some of the cases of special incidence of general diseases on women may be explained by the indirect effect of primary disorders of the female organs; (2) others by the more emotional tendency, the greater liability to disturbance and the smaller power of self-restraint shown by the majority of women compared with the majority of men; (3) some of the cases of special incidence of general diseases on men may be referred to their more exposed and hazardous life, to their different physical and mental education, to their greater liability to the results of calculus and stricture, and their more general propensity to gluttony and drink.

Under the first head comes the frequency of cancer of the breast in women. This, along with the great proclivity of the uterus to cancer, makes the total mortality from carcinoma considerably greater in women than in men.[2] To the same indirect uterine influence may be referred a certain number of cases of cardiac disease dependent on the high tension of the blood, the "physiological plethora" of pregnancy, as Dr. Barnes has termed it; a large number of cases of hydronephrosis and consecutive Bright's disease, which result from prolapse of the uterus; the majority of cases of severe anæmia with constipation; and perhaps a third of the cases of gutta rosea in women which depend upon disordered menstruation or on the menopause. Also for the rarity of gonorrhœal synovitis and the greater frequency of peritonitis in women.

Under the second head of "mental constitution" we may rank the prevalence among women of functional nervous disorders to which the adjective hysterical has (not without reason) been applied, with comparative rarity of the more fixed and permanent fancies to which (also not without reason) the title "hypochondria" has been given; the frequency of cardiac palpitation and other functional disorders of the heart, including perhaps that most singular of maladies exophthalmic goitre; and the uncertainty of both symptoms and events which attends cases of paraplegia in women.

Under the third head of "feminine habits" fall the proclivity of women to headache and neuralgia, constipation and dyspepsia (including that caused by the abuse of tea-drinking), obesity and anæmia from want of fresh air and active exercise; as well as their comparative immunity from atheromatous disease of the heart and arteries, particularly from aneurysm and from aortic (lævo-sigmoid) valvular lesions, from delirium tremens, from cirrhosis of the liver, and from gout; also from hernia, volvulus and other forms of intestinal obstruction which depend on strangulation of previously healthy gut, compared with their liability to those more chronic forms of obstruction which are caused by adhesions about the pelvic organs. The several effects above mentioned are due to the indirect working of disorders of the uterus and ovaries, the ready susceptibility of the nervous system, the comparative absence of exposure to weather and accident, of muscular labour and strain, and the diet, clothing, and habits which civilised life impose upon women. All of these have their full play during the time of ovarian activity, and are much more restricted before and after that middle period of life, in girls under puberty, and in women after the menopause. Accordingly, we do not find that the specially female maladies are nearly so common in childhood or in old age. On the other hand, we do find that men of feminine impressibility suffer from hysteria, from palpitations and syncope, or, to use our fathers' terms, young and emotional men are liable to "the vapours" and to "swoon."

[1] This is done by Dr. William Ogle in the instructive reports of the Registrar-General. The problems of statistics have been scientifically treated in Dr. Longstaff's excellent monograph on the subject.

[2] The Registrar-General's returns show that from 1848 to 1890 there were 167,734 deaths from cancer in women and only 84,913 in men.

Digitized by Google

There still remain instances of marked sexual proclivity without any plausible explanation. Male children (allowing for their greater number) are more liable than female to tubercular meningitis, laryngismus stridulus, and tetanilla. In patients of all ages, most structural diseases of the nervous system are decidedly more frequent in men than in women. I do not refer to apoplexy and hemiplegia, because, so far as these clinical diseases depend on cerebral hæmorrhage, they are not nervous, but vascular in origin; nor to tetanus, because that is an infective and traumatic disease like pyæmia. But why should cases of acute myelitis, of progressive muscular atrophy (including Cruveilhier's palsy, bulbar paralysis, and Duchenne's pseudo-hypertrophic paralysis), of tabes, of cerebral abscess and tumours, and of general paralysis of the insane be so far more common among men than among women?[3] Why, again, while the atrophic forms of paralysis are so far more common among males, is the essential acute special paralysis, which is known as distinctively children's, so impartial between the sexes?

The nervous affections in which the female sex is more or less predominant are hysteria, including hystero-epilepsy, syncope and palpitation, with some forms of emotional insanity; the eclampsia of pregnancy, and puerperal mania—all of which are etiologically related to female physiology. Megrim or sick headache and neuralgia of the fifth pair of nerve are certainly more common in women than in men, while the opposite is the case with sciatica—a hint perhaps that it is in most cases a neuritis, not a true neuralgia. Chorea is more common in girls than in boys under puberty. Thus, of first attacks under sixteen under my own care, there were thirty-four in boys to seventy in girls. If all attacks were counted the contrast was still greater. But, as we know, chorea is far more rare in grown men compared with grown women. My cases between sixteen and twenty-six are thirteen men to twenty-six women. This relative persistency of a children's malady in the female sex is an interesting point. For comparative morphology teaches that the male organism is more differentiated than the female, further removed from the embryo condition; hence, we should expect that the pathology of the adult female would approach more nearly than that of the adult male to the pathology of the child. In a somewhat similar way we may "explain"—i.e., refer to a wider *group* of facts—the fact that some of the diseases of women after the menopause approach nearer to those of men—as, for instance, gout.[4]

To complete the list of diseases in which the female sex operates as a powerful predisposing or favouring cause we may mention myxœdema, bronchocele (endemic and exophthalmic), gall-stones, acute yellow atrophy of the liver, floating kidney, osteo-arthritis (particularly when occurring early and affecting the fingers), mollities ossium, pemphigus, sclerodermia, and xanthelasma. Among those to which the male sex predisposes are plastic bronchitis, hay fever, asthma, angina pectoris, atheroma with aortic valvular (sigmoid) disease, aneurysm, typhlitis, invagination of the bowels (but in children only, not in adults) and strangulation generally (particularly and almost exclusively that due to the presence of a diverticulum ilii), hepatic abscess, cirrhosis, paroxysmal hæmoglobinuria, diabetes, Addison's disease of the adrenals, calculus, gout, hæmophilia, and the severer forms of anæmia, except chlorosis—viz., leuchæmia, anæmia lymphatica, and Addison's idiopathic anæmia.

Of diseases due to bacteria, parasites, and fungi, few show any etiological relation to sex; such exceptions as tetanus, glanders, and anthrax are, like lead-poisoning and grinders' phthisis, sufficiently explained by the greater exposure of men to opportunities of contracting them. But, on the whole, scarlet fever, typhus and cholera, hydatids, scabies, and ringworm are impartial in their incidence, and find equally suitable soil in either sex. One exception appears to be whooping-cough, which is either less common or less fatal among boys than among girls.

Two important diseases have been asserted to be etiologically related to sex, which are, I believe, really indifferent in this respect. One is gastric ulcer. Brinton and Wilson Fox make it more than twice as frequent in women as in men; and von Ziemssen's numbers (confirmed by necropsy) were thirty-five to fifteen. That the usually simple, punched-out, perforating ulcer of the stomach—first described by Abercrombie, and subsequently by Cruveilhier and Rokitansky—is very common amongst young women there is no doubt, but it is far from being rare in the male sex and in later periods of life. I was first struck with this among private cases, for I have seen the disease in an old gentleman aged seventy-eight, who recovered, and in a lady over seventy, who died; on the whole, more often in young men than in young women. Thinking this was an accident of too small a number of instances, I found (with the help of M. Keiffenheim) the following results: Of 93 cases in Guy's Hospital which were diagnosed as gastric ulcer and went out relieved or cured, 33 were men and 60 women; but of 101 cases which died in hospital 59 were men and only 42 women. This may mean that our diagnosis has suffered from an insufficient basis of morbid anatomy, or it may show that more women than men recover.

The other is the idiopathic form of anæmia which was fully described by Addison in 1885, recognised by English writers and by Trousseau, imperfectly described by Lebert in 1858, and rediscovered and renamed in 1871 by Biermer. This physician working at Zurich, Immermann at Basle, Quincke at Berne (as well as Lebert at Zurich), agreed in stating that what they called "progressive pernicious anæmia" was far more common in women than in men; and the statement was naturally confirmed by Professor Gusserow from a gynæcological point of view. A study of their cases, and of those collected by Eichhorst in his monograph on anæmia, shows that some of them would in England be called chlorosis, and others would be regarded as anæmia secondary to hard and scanty fare, gastric disturbance, diarrhœa, hæmorrhagia, or lactation. On this principle we might add cases of "pernicious" anæmia in both sexes due to cardiac or renal disease, plumbism, or cancer, and, as a matter of fact, such cases have been admitted by certain writers. The important fact discovered by Addison has thus been lost sight of: that there is a severe and fatal form of anæmia which is idiopathic, primary, essential. If we exclude the secondary and spurious cases, and keep to his original and masterly account of the disease, we shall find that it is as common among men as women. And this agrees with its true pathology—for it is quite distinct from chlorosis, and is naturally allied with the other essential and grave forms of bloodlessness which we know as leuchæmia and Hodgkin's disease, all of which are more common in the male than the female sex; all of which, I may add, are unbenefited by steel, but sometimes cured and often relieved by arsenic.

Age in its bearing on etiology.—The predisposition of certain ages to certain diseases is often very remarkable. In some respects childhood and second childhood agree; their liability to death from bronchitis and diarrhœa argues a less power of resistance, which is also seen in the difficulty of maintaining animal heat in both extremes of life. The easy vomiting of children may be classed with the preponderance of reflex action, the spinal system being active and sensitive. Hence the prompt and marked character of the superficial reflexes (plantar, palmar, or cremasteric) in children, their ready laughter when tickled, their liability to convulsions. With the same physiological condition we may associate the presence of tetanilla and carpopedal contractions, trismus and laryngismus stridulus, infantile convulsions, and particularly those which take the place of rigor in an adult. To the same activity of reflex action we may perhaps ascribe the remarkable frequency of invagination of the intestines in children and the spasmodic element of diphtheria and catarrhal laryngitis, as well as of true asthma. Children are dependent for their food on others, and hence are liable to suffer from an insufficient or ill-constructed dietary. This is probably the cause of rickets and also of infantile diarrhœa and choleraic diarrhœa, so-called dysentery, and marasmus. The peculiar liability of children to certain forms of atrophic—including pseudo-hypertrophic—spinal paralysis has not, I believe, received any explanation. The predominance of children among those suffering from epidemic specific fevers is, no doubt, due to most adults being protected by a previous attack; for when small-pox or measles invades a virgin population all ages are indiscriminately seized.

One common character of children's diseases is that they are generalised in distribution. Tubercle invades a greater number of organs, phthisis is less confined to the apices,

[3] Traumatism cannot explain the preponderance of male patients with cerebral tumour, since Dr. Hale White has found that the same preponderance applies to male children and to tubercular growths.—*Guy's Hospital Reports*, vol. xliii., p. 118.

[4] Hipp. Aphor., vii., 29.

Digitized by Google

pericarditis and endocarditis are more constantly associated, and diseases of the skin keep far less definitely to their usual localities, as, for instance, psoriasis and scabies. This peculiarity may perhaps be referred to the greater differentiation of the tissues in an adult.

Race and climate.—The effects of climate as an element in the causation of diseases are doubtless important, interesting, and instructive. But exact accounts of endemic diseases and of local modifications of diseases are still rare. I could give no facts of value from personal knowledge, and therefore prefer to pass over this part of my subject.[5] One of the difficulties of geographical pathology lies in separating the effects of climate from those of race and manner of living. That the marked racial differences between, for example, Europeans, negroes, and Chinese affect their functions as well as their mental character, and their reaction to disease as well as their normal physiology, there can be little doubt. But on the whole it seems probable that even in such extreme cases the differences are but small. The surprising lack of sensibility to pain which is characteristic of many races is rather due to undeveloped mental qualities than to ethnological peculiarity. Negroes are said to be very little subject to malaria; but a statement which I made to this effect has been corrected by those who speak with the authority of personal experience. Nevertheless, they must be less liable than Europeans, or how do they live where white men die? At present we may, I believe, state that there is no infection against which any race of mankind is immune; that there is no disease peculiar to any nation, or from which any nation is exempt; and that there is no drug known, whether poisonous or medicinal, which fails to exert its ordinary physiological effects upon any community of mankind.

Among the few exceptions to the uniformity of geographical distribution which we observe in our own islands may be mentioned the frequency of osteo-arthritis in Ireland, the rarity of hydatids and the comparative frequency of favus in Scotland, the absence of malarial diseases in Ireland, the prevalence of urinary calculus in Norfolk, and of endemic bronchocele in Derbyshire. Mr. Cadge finds that the frequency of stone is limited to uric-acid calculi. Those of oxalate of lime are not more common, perhaps less common, than elsewhere. It is remarkable that these uric-acid calculi, though common in boys, are only so in hospital practice. A late eminent lithotomist is said to have remarked, with a sigh, that he only once received a fee for cutting a child for stone.

Has change of climate within historical times brought about change of diseases? I think we may assert that, with a few important exceptions, such as the draining which has led to the general disappearance of malaria, and the improved habitations of the poor, which have made plague unknown and typhus rare, no such changes have taken place; and in particular that there is no foundation for the opinion that in former time the English spring was milder than at present. "The uncertain glory of an April day" was as uncertain at the close of the sixteenth as at the close of the nineteenth century. In the seventeenth the great Earl of Verulam met his death from standing in the snow on Highgate Hill on Easter Monday, and Evelyn remarks, under date March 27th, 1681: "An extraordinary sharp cold spring, not yet a leaf on the trees." In the eighteenth century Horace Walpole writes that "the spring has set in with its usual severity"; and the contrast between poetical description of the "ethereal mildness of spring" and its actual inclemency had become a commonplace of satire.

Occupation.—The importance of certain trades as causes of disease is well known; so well that there is little room for discussion. The effect of lead poisoning as a predisposing cause of gout and Bright's disease, and a direct cause of colic, paralysis, and abortion, has been dealt with from extensive personal knowledge by our late Goulstonian lecturer, Dr. Thomas Oliver. Mercurial tremors are rarely seen now; we had the first case I have seen for twenty years in Guy's Hospital last November. We can often cure and prevent chronic diarrhœa and other disorders which arise from arsenical poisoning by detecting their origin. The group of conditions which have been conveniently named in common "pneumoconiosis" will engage our attention as powerful predisposing causes of phthisis.

Overwork.—Before leaving this part of my subject, however, we must ask whether laborious occupations in themselves may lead to premature strain of the body or mind, and so to degeneration and disease. Here, I think, we must distinguish. Aneurysm, emphysema, and some forms of cardiac hypertrophy undoubtedly may be the result of overstrained and too violent or prolonged exertion, from mechanical stretching of the great arteries by movements of the arms, from high blood pressure, excessive calls on the heart, and over-long suspension of respiration, as in muscular efforts with a closed glottis. We see similar results in horses which are put to hard work at too early an age, and there is no reason to doubt the operation of such causes of disease in man. But their operation is limited to the production of certain definite lesions, and there is no evidence that harm is done, disease brought on, or life shortened by what is commonly known as work, whether mental, physical, or a combination of the two. The vanity of human nature is tickled by ascribing its disorders to such respectable antecedents as industry, energy, and intellectual activity. We must all have felt this when the obvious results of habitual idleness or gluttony are ascribed by a patient or his wife to an overtaxed brain or too strenuous devotion to business—especially in the public service. There is no fear of any one of us using our brains too much for our health, nor do I believe that mental labour or honest work of any kind interferes with health or shortens life a day. Even if it did, who would not rather be worn in use than rust in idleness? Who would not choose a short-spanned life filled full of action and of thought, of sorrow and of joy, of effort and endurance, of enjoyment of living oneself, and helpful service to others, rather than to wear out a tedious existence of monotonous ease.

There is, I repeat, no reason to believe that work in itself is injurious, even if it encroach on the hours of sleep. Nature will take care of herself, and irrepressible drowsiness will bring the needed rest if it be not driven away by artificial means. The evil results of excitement in the gambler, or of anxiety in the man who habitually lives beyond his means, are indirect. Such patients go too long without food, and then eat more than they can digest, for their meals are irregular and hurried; or they take stimulants from time to time to excite them for the moment, or sedatives to give the repose which they have not fairly earned.

Before passing from this part of my subject, permit me a word of protest against the assumption, which has become a commonplace of newspapers and of conversation, that the present age, the close of this nineteenth century, is fuller than any other of what is called "worry" and anxiety, mental excitement, over-strung nerves, and what not. It is gravely asserted that railways and telegraphs and the modern race for success are shortening life in Europe generally, and in England and America in particular; that there is an enormous increase of what are called nervous disorders; and that the neurotic temperament or type or diathesis which now prevails is intolerant of the heroic means of combating diseases which were well borne by such dull-witted fellows as Steele or Johnson, and by the comfortable, prosaic, easy-living men who saw the mutiny of the Nore and Napoleon's army gathered to invade our shores. Surely we are complimenting and pitying ourselves without cause. What are the hardships of a railway journey to Bristol or to Edinburgh compared with those of a journey by coach? What are the trivial anxieties of a citizen's life from telephones and telegrams, rates and taxes, advertising druggists, and School Board elections, compared with those of previous generations, when few men had not been robbed on the highway or otherwise put in personal peril, and when the citizens of many towns in the king's dominions had experienced a siege, a famine, or a pestilence. We may be sure that family troubles, misunderstandings and quarrels, disappointments and annoyances, bodily aches and pains, bills that cannot be paid, and accounts that will not balance, were just as common a hundred years ago as now—in the days of Horace or of Lucian, as in those of the *Spectator* and the *Rambler*.[6]

[5] I cannot but refer in this connexion to the valuable reports from the medical officers living in the Chinese ports which have been drawn up and published by the wise forethought of Sir Robert Hart.

[6] That life is in every way easier than it was a little reflection will convince us, and perhaps there is no better illustration of the fact than to contrast the annoyance, cold, and vexation which must have been constantly endured while trying to strike a light with a tinder box, compared with the ease, certainty, and rapidity of the lucifer match, or the still more rapid, easy and brilliant electric light. Let me recommend the perusal of a somewhat prolix, but not uninteresting book, which obtained the honour of a review in the *Edinburgh Review*, by Sir Walter Scott, called "The Miseries of Life." It was published in 1806

The complaints we now hear were just as common fifty or a hundred years ago; the nation has been going to ruin ever since it was a nation, the present generation has always been degenerate, more feeble, more vicious, and more diseased than any which preceded it; but at the same time more sensitive, more interesting, more pitiable than any other, and, above all, gifted amid the general decay with a few superior intellects which could appreciate and describe the evils which they never attempted to cure. Hypnotism is not a more silly business than clairvoyance, nor that than mesmerism and phrenology, and the worst performances at Salpêtrière are only reproductions of mediæval cases of possession. If we may judge from plays and novels, fainting and the vapours are much less common in the nineteenth than in the eighteenth century. Men in general probably live a more domestic, healthful, and sober life than a hundred years ago; women are probably less nervous and bear and rear larger families; while children, both rich and poor, are certainly better clothed, better fed, and grow up into taller, stronger, and healthier men and women.

Local conditions as etiological factors.—When morbid anatomy was first studied by Rokitansky and his contemporaries, it was natural to make a list of all the known morbid processes, and then to apply them to each of the organs and tissues, so that one would have to describe hypertrophy and atrophy, fatty, calcareous, and pigmental degeneration, inflammation, fibroma, enchondroma, and carcinoma, malformations, and the presence of animal or vegetable parasites for every organ and tissue alike—for the parotid gland and the crystalline lens, for muscular and for adipose tissue. Such a preliminary method was valuable from its thoroughness; but long before the complete schedule was applied to every organ, it was clear that the various morbid lesions are *not* indiscriminately distributed over the body. Each general process is modified by the tissue affected, some organs are prone to certain forms of disease and are absolutely free from others, and in almost every case the common type appears under different local forms. Thus, speaking generally, we may affirm that some organs, like the small intestine, the salivary glands, and the pancreas, are almost exempt from disease, except by such specific processes as enteric fever, or tubercular ulceration, or mumps. We may state that suppurative inflammation never befalls the brain, the lungs, the liver, the spleen, the kidneys, or the testes—in fact, any of the solid viscera—except from infection or local injury; while, on the contrary, suppuration is a frequent and easy event in the case of skin, mucous membranes, connective tissue, and bone. We may affirm that tubercular inflammation, while extremely apt to affect the lymphatic tissue of bones, the lymph follicles of the intestine, and the lymph glands, as a primary process, is never seen in the great mass of lymphatic tissue formed by the spleen except by secondary infection; while, on the contrary, primary tubercle is common in the brain, the testis, and adrenal body, where lymphatic tissue is almost absent. With respect to tumours, I remember as a student supposing that chondroma, fibroma, lipoma, and the rest were just as common in one place as another, and was surprised to find that all the fatty tumours I saw were under the skin, and all the enchondromata connected with bone. It was then, strangely enough, not suspected that carcinoma had any special laws of distribution. This was partly because histologists had not yet definitely separated true carcinoma from other forms of malignant disease; at present we all, I suppose, accept Waldeyer's doctrine that "true" carcinoma only begins in an epithelial surface. This, however, is not all, for the epithelial or keratoid form has its own seats of predilection, distinct from the other kinds of cancer, and the same applies to the colloid and adenoid varieties. But the localisation of cancer is not only histological; for the mucous membrane of the small intestine, though of the same general structure as that of the rectum, is one of the rarest, as the latter is one of the most frequent, seats of the disease, and the acini of the parotid are as distinguished by their immunity as from those of the mamma by their proclivity to cancer. In the etiology of this disease it is not surely without meaning that its favourite seats, irrespective of histological structure, are the lips, tongue and throat, the œsophagus, pylorus, and rectum, the places where there is most friction.

Another remarkable law in the distribution of cancer is that those organs, as the uterus, the mamma, the stomach, the rectum, and the testis, which are the most frequent seats of primary carcinoma, rarely become affected by secondary growths; while the liver, the lungs, the lymph glands, and the serous membranes, while constantly affected by secondary, are rarely the seat of primary cancer. This proves, surely, that secondary growths are not the result of a general dyscrasia or predisposition, but are strictly derived from primary, by direct transmission through veins and lymphatics; and that primary cancer is really homologous, and not heterologous, in its origin, autochthonous and not immigrant.

In the lungs, again, phthisis chooses the apices, and not only the apices, but the highest point of the inferior lobe; while pneumonia almost as constantly begins below and spreads upwards. But it is in the skin that we find this principle of local predilection most strikingly exemplified, because here the histological characters are essentially the same. We may no doubt explain certain peculiarities as due to the greater abundance of sweat glands, or sebaceous secretion, or to the size and length of the hair, or to exposure to cold or to friction. But there remain many topographical peculiarities which are at present inexplicable. The striking and opposite localisation of psoriasis and eczema, the scarcely less marked local distribution of erythema, of lupus, of lichenruber, of erythematous lupus, of xanthelasma, and many other cutaneous diseases, depends upon etiological laws of which at present we have no conception. All we can say is that psoriasis, for instance, affects the left elbow because it is most like the right, and affects both knees because they are most like the elbows.

The mysterious etiological factor symmetry, of which so much has been written, may be reduced to two cases. In one the same affection is seen on both palms, on both soles, over both olecrana, or both popliteal spaces, because the corresponding sides of the body resemble each other more closely than anything else in nature. Thus psoriasis is symmetrical because it affects the same kind of skin, and because there is a right and left elbow, in the same way as Bright's disease and phthisis are symmetrical because they affect renal and pulmonary tissue respectively. The other case of symmetry in which a disease affects the surface of the whole body has sometimes been held to prove that the disease is "constitutional," or has its origin in the blood or nervous system. But surely this symmetry is not of genuine etiological moment at all, it is merely the result of widespread disturbances affecting a symmetrical organism, and such accidental bilateral symmetry would be lost in the case of a man with a distorted spine—it would be asymmetry in a turbot or a snail, and pentagonal symmetry in a starfish.

We shall find many illustrations of local modifications of general morbid processes in discussing the etiology of certain particular diseases to which I shall invite your attention at my next lecture.

CERTAIN QUESTIONS ON THE TREATMENT OF DIABETES.[1]

BY CHAS. H. RALFE, M.D.CAMB., F.R.C.P.LOND.,
PHYSICIAN TO THE LONDON HOSPITAL, ETC.

THE questions which I propose submitting for consideration are—1. In cases of confirmed[2] diabetes running a protracted course, may any relaxations from the usual dietetic restrictions be permitted? 2. In such cases, at what period of the disease should opium or its derivatives be commenced, and how far may they be pushed? Besides these, I had in view a third—viz., What other measures, in addition to diet and opium, have been found useful in checking the disease or in relieving special symptoms? But on consideration, when I came to write this paper, I found that the addition of this third question would make the communication too lengthy; besides which, I thought it would distract discussion from the other two, which are, to my mind, the most important. At first sight, it may be thought that these questions are superfluous, especially in this country, where the insistance on the maintenance of a rigid dietary, combined with the administration of opium or its derivatives, has been taught in our

[1] Paper read before the Medical Society of London, March 14th, 1892.
[2] Cases of transient and gouty glycosuria and intermittent forms of diabetes in which assimilation is for a time restored are not considered in this paper.

Digitized by Google

schools and endorsed in our text-books. But of late views have sprung up which have had a tendency to impair this teaching, especially as regards the necessity for maintaining a strict adherence to a proteid diet as the essential point in the treatment of the disease. This laxity with respect to a canon law first originated, no doubt, with the introduction of the so-called "skim-milk cure," and as at that time the distinction between diabetes and transient glycosuria was not clearly defined, several cases of the latter were cured which were supposed to have been of the nature of true diabetes; and though Dr. Pavy promptly disclosed the fallacy, and again placed the ban against milk in confirmed cases of diabetes, still there has remained a leaven of the heresy among many practitioners, not merely in not excluding milk from the dietary, but even in ordering it in very considerable amounts. But milk is not the only article that has crept in unawares into the fold of a pure dietary, and many of the continental physicians now permit a dietary which can no longer be called restricted. Thus Dr. Seegen[3] permits a small quantity of wheaten bread and subacid fruits, such as strawberries, &c.; Dr. Colquard[4] and Dr. Dujardin-Beaumetz[5] allow mashed potatoes instead of gluten bread; whilst in America, in a well-known work on Practical Medicine,[6] the diet table drawn up by Dr. Austin Flint[7] permits of asparagus, gooseberries, cherries, plums, and strawberries. It is true, no doubt, that those who permit these relaxations do not question the theoretic considerations on which the absolute restricted dietary is founded; they only deny the possibility of carrying it out to its full extent, and point out the direction in which relaxation may be least harmful to the patient. The point, therefore, I would draw attention to is whether such relaxation should be forbidden as aggravating the disease, or forced on us as a compromise.

With regard to the second question but little information exists; for though the authorities on this subject are eloquent on the effects opium and its derivatives have on the course of the disease, few, if any, rules are given for guidance.

The answers to these questions will of course greatly depend upon our clinical experience, and the views we have formed as to the nature and progress of the cases that have come under our observation. Most authorities now recognise two forms of confirmed diabetes, which they classify as—(1) neurogenic, usually coming on suddenly as the result of some nervous shock, and running a more or less acute course; (2) constitutional, gradually supervening as the result of some taint—gouty, rheumatic, syphilitic, or tubercular—the progress of which is usually protracted. But of late I have accepted a distinction between the two forms which I think indicates more closely their relationship and better represents their clinical features than the above-mentioned classification, which is based only on etiological conditions, and which I would describe as: 1. An alimentary diabetes, which can at first be entirely controlled by diet; but gradually this control is lost, and sugar reappears in the urine in spite of all restriction. This form is most commonly associated with a constitutional taint of some kind, though it sometimes, but less frequently, is found in cases of neurogenic origin. 2. General diabetes, in which, from the earliest onset, a restricted diet fails to remove entirely the sugar from the urine, whilst the glycosuria is out of all proportion to the food (of all kinds) ingested. This form is common in cases of neurogenic origin, and is specially characteristic of pancreatic diabetes. Whence comes the sugar in urine which is not derived from the starchy and saccharine materials of the food has always been a problem. That it is not altogether furnished by the metabolism of the proteid elements of the food—which was formerly supposed—is shown by the fact that it is often in considerable excess of what could be furnished by the proteid diet the patient was on; besides, as I have observed in carefully dieted cases, hardly any reduction, certainly not at all proportionately, follows a diminution of the proteid food—a fact which points to the source of the supply being from the tissues themselves; and, indeed, we now know that other tissues besides the hepatic furnish glycogen. What, then, happens in the two forms of diabetes we are considering is that in the milder and alimentary form the power of assimilating starch and sugar is only lost as far as the liver is concerned; but after a time, perhaps from the passage of sugar from the liver into the circulation, the tissues lose the power of transforming glycogen into energy or storing it up as fat, or, as some are now endeavouring to show, the blood loses its glycolytic or sugar-destroying power, owing to the absence of a ferment which is said to be normally furnished chiefly by the pancreas, but also by other glands. It is then that the diabetes may be said to become general. Out of a total of sugar excreted by the urine, a portion still remains removable by abstinence from starchy and saccharine food, but as the case progresses the proportion between this removable sugar and that which is not affected by a strict diet becomes more and more marked. Thus in a mild case in an early stage the total amount of sugar passed in the twenty-four hours was 150 grammes, which on strict diet sank to 30 grammes, or 5 to 1; whereas, in a severe case, one month before death the total amount of sugar was 320 grammes on a mixed diet, which was reduced by strict diet 190 grammes, or a proportion of 1 to 1·6. In short, the difference between the removable and non-removable sugar in a case of diabetes is one of considerable value for the purpose of prognosis, for any sudden increase in the proportion of the latter, though there may not be any actual increase in the total of sugar excreted, is always indicative of an exacerbation of the disease.

Rollo was the first to point out the extreme susceptibility of cases of diabetes, in which the sugar excretion had been stopped by diet, to relapse on very slight and very inadequate resumption of sugar. "Thus, half a biscuit, such as sold by confectioners at three a penny, has," he says, "brought back the disorder in full force," and my own observations have convinced me of the fact that in alimentary diabetes any increase of sugar ingested is always followed by an excretion of sugar, often above that amount. On the other hand, in general diabetes, although it is manifest the assimilative processes are lowered by the persistent presence of sugar in the blood, still the proportionate effect on the excretion of sugar is not so marked as in the purely alimentary form. Thus in a case in which the proportion of removable sugar was as 5 to 1 of non-removable, the resumption of mixed diet caused an immediate increase of the total sugar, amounting to 80 per cent.; whilst in a case in which the proportion of removable sugar was as 1 to 2 of non-removable, the resumption of the same dietary only caused a rise of 27 per cent. At first this would seem to tell in favour of a partial toleration of a less restricted diet in protracted cases of diabetes, especially when the proportion of non-removable sugar is high; but further observations show that though the increase per cent. in the amount of sugar in these cases is not so large as in the alimentary ones, still the resumption of saccharine food, even in a limited extent, acts adversely against the assimilative processes in the body, as is shown by the fact that generally when strict diet is again resumed, we find the proportion between the sugar removable by diet to be decreased; whereas the non-removable sugar is found to be increased. Thus, for instance, when before the resumption of a mixed diet the proportion of removable sugar was 3 to 1·5 of non-removable, after three weeks of mixed diet, on the return to an absolutely restricted diet the proportion became 2 to 2·5, showing that persistent supply of saccharine food had further lowered the assimiiative processes in the body. This fact, therefore, seems to tell conclusively against any relaxation of the restricted dietary in this form of diabetes; whilst the extreme sensitiveness to the minutest particle of starch and saccharine food exhibited when the glycosuria is still controlled by absolute restriction of the diet tells equally against its resumption in this stage of the disorder.

The next consideration is whether the advantages gained by a strict adherence to an absolute diet of proteid substances by diminishing the amount of sugar in the blood, and so checking the tendency to a further lowering of the assimilative processes in the body and controlling the extreme diuresis, may not be gained at too great an expense to the patient's well-being, and that some benefit may be derived in other directions by permitting a slight relaxation from too rigid a proteid dietary, and whether its too long continuance is not in itself a danger by causing the formation in excess of bodies such as the

morbid products of proteid metabolism. This is a question that requires further investigation before a decision can be given, but there are certain facts already ascertained which certainly seem to point in that direction. Dr. Wright, in his Grocers' Research Scholarship lecture,[8] stated that in the artificially induced diabetes of an animal kept entirely without food the same morbid products of proteid metabolism were found in the urine as are found in human diabetes, which, as the animal was in a state of inanition, must have been furnished by the imperfect metabolism of its proteid tissues. To this it may be answered that certain tribes live almost exclusively on meat from year's end to year's end; as do hunters for very long periods at a time without appearing to be in any way injuriously affected by diet. But the powers of assimilation of healthy active savages or vigorous hunters is very different from the feeble diabetic. In scurvy—a disease as I have endeavoured to show brought about by the withdrawal of alkaline salts and the increase of acid salts—so long as the patient remains vigorous, active, and cheerful, the disease is kept at bay; but the moment the vital powers are lowered from exposure, fatigue, or anxiety, then all the consequences of the diminished alkalinity of his blood are experienced. So in diabetes, though there is no actual withdrawal of the alkaline salts, there is with the flesh diet a positive entrance of an increased amount of acid salts into the body. These possibly at an early period of the disease, whilst the patient is still fairly vigorous, are eliminated by the kidneys, but when the bodily powers begin to fail they accumulate to a dangerous extent. Added to this is the fact that with increased feebleness the power of digesting proteid material is lessened, and consequently the risk of the formation of toxic bodies in the intestine is increased.

(To be concluded.)

THE INFLUENCE OF MENTAL DISTURBANCE IN PRODUCING ORGANIC DISEASE.[1]

BY H. GRABHAM LYS, M.D. LOND.

IN the following paper on the influence of mental disturbance in producing disease, I intend to limit myself almost entirely to what I think may fairly be termed "organic disease"—disease in which there is some profound change of nutrition or persistent perversion of function. The influence of mind on body in its widest application is far too extensive a subject to deal with in one article, and although from many points of view it would be advantageous to dwell upon functional derangement from mental disturbance before entering upon the genesis of more profound disease, I shall avoid it except in so far as it exemplifies this proposition, that functional derangement is a frequent antecedent of organic disease. I hope that I shall make evident the truth of this in more than one instance. The limitation that I have chosen has the advantage that it deals only with that form of disease which we are all of us, in our hospital life more especially, learning of. It will follow, too, that if I awaken interest in the dependence of organic disease on mental influence, the source of minor diseases will be readily appreciated and the lesson in therapeutics none the less impressed. In most of the cases where disease has long been known to have a definite relation to mental disturbance no effort seems to have been made to trace the links in pathology intermediate between the cause and effect. I shall endeavour to trace to mental causes, through the medium of increased arterial tension, certain cardiac and arterial degenerations which, so far as I know, have not been so referred. Beyond this class I fear I shall be able to do little but emphasise more or less well-known facts.

Atheroma.—First, then, I will deal with atheroma. Atheroma has been universally referred to increased arterial tension; and the causes of increased tension have been enumerated as Bright's disease and the arterio-capillary fibrosis, or muscular hypertrophy of arterioles, associated therewith; and second, intermittent bodily exertion. It is doubtful whether syphilis acts as a cause, unless by syphilitic arteritis and fibroid induration of viscera obstructing the circulation. In old age it may, of course, exist in proportion with the wearing out of the rest of the body without indicating excessive strain or pathological significance. Now, while there can be no doubt that intermittent exertion throws a great strain on the arterial system and leads to atheroma, I think that no long experience is required to convince one that many cases are referable neither to Bright's disease nor bodily exertion. And it seems to me strange that mental influences have not found a place here; it has long been known, and perhaps more recognised a generation ago, before physical examination became so refined, that not only temporary vaso-motor changes, such as occur in blushing or in the whiteness of rage, might be due to emotion, but also that persistent or repeated high tension often resulted from anxiety or mental distress, and accompanied a definite train of symptoms. Dr. Clifford Allbutt mentions the case of a young man whose pulse tracing during twelve months' domestic anxiety showed, on comparison with that before and after, a marked and persistent increase of tension. I have been at considerable pains to obtain some graphic illustration of this fact; but sphygmograms at all times require practice in taking and experience in interpreting, and it is not easy at will to produce such states of emotion as would afford a fair test. When one finds high tension in a patient suffering from anxiety, it is not often that we have any tracing of the pulse before the mental disturbance. The finger, however, will not fail to make the fact evident to anyone who studies the indications of the pulse and chooses to make trial of the fact. I need, indeed, hardly go beyond broad clinical experience to bear out this thesis; why so often does a person fall into a fit of apoplexy or an aneurysm rupture on some sudden mental disturbance? Can it be other than an increase of arterial tension? I shall refer also presently to the pathology of angina pectoris. Case upon case might be quoted where there has been an entire absence of history of such bodily exertion as does give rise to atheroma, where even microscopical examination has shown an entire absence of any thickening of the arterioles, and where history of the mental characteristics has shown that this was the source from which the body had been put to strain; and if atheroma is acknowledged to be due to mental disturbance, then also the results of the arterial disease—such as aneurysm and cerebral hæmorrhage—must be referred to it.

Dilated heart.—Like atheroma, primary dilatation of the left ventricle owns Bright's disease and intermittent severe exertion as its chief causes, but like atheroma it can often be traced to neither; more often than atheroma it is a senile change, and it has been attempted to refer it to degenerative changes in the heart muscle in these cases, perhaps, more than to capillary resistance. But sometimes cases occur in younger people, in whom there is no reason to assume a failure of general nutrition prior to the heart failure, and in whom it seems unreasonable to assume cardiac muscle degeneration; in these, again, I believe the cause is to be found in frequently repeated mental disturbance increasing arterial tension. It seems to be that, as in many analogous instances, the increased tension tends to persist in the interval and become habit, and so the arterial tension becomes permanently raised. But there are yet other cases of dilatation of the left ventricle traceable to mental causes apparently not through the medium of increased arterial tension—cases of a functional derangement, palpitation gradually passing into definite organic disease, hypertrophy and dilatation. How such an effect depends upon the cause is not altogether clear. I think it is perfectly evident that there does occur a class of cases in which palpitation is the primary condition and is followed by hypertrophy and dilatation, and the only question that seems to me to arise is whether increased frequency of heart does give rise in such cases to increased tension. So far as I have had opportunity of clinical observation I am convinced that in such cases there is no rise of tension; both in Graves' disease and transient palpitation the pulse tension is definitely not raised; I think it will be found that with palpitation due to emotion goes vaso-motor dilatation—blushing; and, *vice versâ*, that such emotions as cause vaso-motor constriction and increased tension are not accompanied by palpitation. And I think that these facts are borne out by physiological teaching. "The rate of the heart beat," says Foster, "is in inverse ratio to the arterial pressure, a rise of pressure being accompanied by a diminution, and a fall of pressure with increase, of pulse

[8] See THE LANCET of Feb. 27th and March 5th, 1892.

[1] A paper read before the London Hospital Medical Society in December, 1888.

Digitized by Google

rate." There is, I understand, a mechanism regulating matters on this principle. One can only suppose, then, that the nutrition of the cardiac muscle is so much interfered with by persistent excessive frequency of action that it yields beneath the normal intra-cardiac pressure. Of course, palpitation due to mental or other causes is usually, like the cause, transitory, and leads to no impairment. The cases which bear out this sequence of events are exophthalmic goitre and persistent palpitation not associated with the other symptoms of this disease: in both hypertrophy and dilatation often become developed. And also cases occurring in the American Civil War and in the British army. The former are reported by Da Costa under the term "irritable heart." He brings forward 300 cases of palpitation in soldiers called from civil pursuits without previous training to active service. In twenty-eight cases out of 100 hypertrophy and dilatation were believed to have been developed. It seems clear that the cases did not occur, even chiefly, in those who had been subjected to hard service, and that they were referable to mere change of habit with which mental influences must have been mixed up. In the British army more stress has been laid upon the prevalence of cardiac dilatation and hypertrophy than upon their antecedents; but it seems clear that the "setting-up" drill is the main factor in inducing it. This drill involves marching, and even doubling, with the chest artificially expanded, so that both inspiration and expiration must be shallow, and it is imposed upon recruits for four hours daily. It is easy to see that this might cause increased tension in the pulmonary circulation, but such would not be the result, I think, in the systemic arterial system. It has been directly observed that during the drill the heart's frequency is increased to about 110, and the respiration to 40, per minute. It may be presumed that the increased heart frequency is here due to the action of deficiently aerated blood on the brain.

Angina pectoris.—I must now return to consider the connexion between angina pectoris and mental disturbance; nothing has been more clearly established by clinical experience than dependence of paroxysms of angina upon rise of arterial tension, confirmed by the brilliant therapeutical success of nitrite of amyl which Dr. Brunton's sphygmographic observations led him to suggest. The exciting causes of angina had long been known in the majority of instances to be physical exertion or emotional excitement, and one would have thought that Dr. Brunton's discovery in 1867 would have naturally led to the increased tension being referred directly to the existing cause; but the almost invariable association of certain organic changes, such as atheroma of the aorta, aneurysm of the base of the aorta, calcification of the coronary arteries, or degenerative lesions of the cardiac nerves and ganglia, seems to have led to a rivalry of the authorities in proving that one or other of these conditions is the essential cause. To me it seems but rational to attribute most of these associated changes—the result of arterial strain—to the repeated occurrence of the same increased tension which finally, in its sudden repetition, produces the struggle of the heart for life, and which constitutes an attack of angina pectoris. The changes in the cardiac nerves and the anglia seem to be secondary to the thickening and induration of the adjacent aorta. It is true that a paroxysm of angina is not always directly referable to either physical exertion or emotional excitement; the great Dr. Arnold of Rugby, it is said, was attacked in his sleep without any warning by his first and fatal paroxysm; it is difficult to say what circumstances can suddenly produce the necessary conditions in these cases; but they are quite exceptional, and I think that mistake has arisen from a too ready assumption that sudden death in a person with the organic changes usually associated with angina pectoris has necessarily been due to that disease. To take John Hunter's case, for instance. He had suffered from angina pectoris for years, but from what can be read of his death it seems that the clinical features of the fatal attack were those of syncope, although probably excited in the same way as his attacks of angina. He dropped down dead, absolutely suddenly, in a fit of anger with the authorities of St. George's Hospital; he had none of the symptoms characteristic of angina, and I contend that had he not been known to suffer from angina no one from his mode of death would have attributed it to that disease. To relate the history of one case of angina which came under my notice: A man in a large way of business in London who went through in the course of a few months a succession of most severe trials, each telling severely on his health, and the last suddenly attended by true angina. The first of these troubles involved separation from his wife, and then in succession at a short interval he lost two of his children. On each of these occasions considerable depression and insomnia followed, and his heart was noticed to become evidently less vigorous and slightly enlarged; then after a few months' anxiety in connexion with his business was followed immediately by repeated attacks of the severest angina. I look, indeed, to the pathology of angina for the strongest confirmation of what I have urged in support of the view that emotional excitement gives rise to increased tension and arterial degeneration. I may just allude here to the increase of cardiac affections, shown by Sir R. Quain during the last generation, coincident with conditions vastly intensifying the worry of life and strain on the feelings.

Graves' disease.—I have already mentioned cases of exophthalmic goitre in which permanent cardiac disease results from the long-continued palpitation. I must now just revert to that disease, to consider whether the theories of its causation by changes in the cervical sympathetic may not be more reasonably supplanted by the view that mental disturbance is responsible for it.[2] It has to be remembered that no one has ever expounded how the symptoms can be due to any one kind of disturbance of the functions of the cervical sympathetic. For the goitre a paretic lesion must be assumed, but then the recognised phenomena of paralysis of the cervical sympathatic are absent, and, further, to explain the palpitation we must have an irritative lesion. No irritative lesion will explain the thyroid enlargement, though the exophthalmos might be assigned to either; but in either case the eye symptoms are incomplete if accounted for by sympathetic lesion. It can hardly be contested that in every case of this disease a morbid mental state of constant character precedes its development. The prominent features of that mental state are depression with extreme irritability; and only as life wears on, and a more placid mental state is established, do the symptoms of this disease subside. The next question obviously is, How does the mental disturbance give rise to this train of symptoms? I think if one does recognise that an antecedent mental state may fairly be held responsible for the subsequent morbid developments, there will be difficulty in refraining from the belief that the exophthalmos and goitre are in some way referable to the palpitation; in every case in which a trustworthy account of the commencement of the disease is available, there appears no doubt that palpitation has preceded the other symptoms by a considerable interval. Slight thyroid enlargement is comparatively so common in girls who suffer only from intermittent palpitation that there is little difficulty in referring it to this cause; and the exophthalmos is the least constant and last developed of the three. I have yet to be convinced that cases occur without palpitation. There has been a tendency, however, among recent writers to attribute this disease to nuclear degeneration. Experiments by Filehne have shown that by dividing the upper part of the restiform bodies to a certain depth exophthalmos and vaso-motor paralysis of certain other areas were produced, although the thyroid did not swell. Thus the conclusion is drawn that the restiform bodies contain the nerve paths of circumscribed portions of the vaso-motor centre which are paralysed in this disease, while the palpitation is attributed to some involvement of the adjacent vagus centre. Graefe's and Stellwag's symptoms are similarly assigned to a central lesion, and Dr. Fitzgerald has remarked upon the occasional association of other central paralyses. I would still hold that the evidence points to the influence of mental disturbance as the cause, and we may gladly accept the subordinate mechanism which these observers are working out, for such of course there must be.

(To be concluded.)

[2] I have lately observed that Dr. Hector Mackenzie has taken a similar view of the pathology of Graves' disease.

CHILDREN'S INFIRMARY, LIVERPOOL.—At a special meeting of the governors, held on the 13th inst., to consider the revised rules, it was resolved to reduce the number of governors necessary to elect a medical officer to forty. The forty governors to be elected would be divided into five groups in rotation.

CURE OF STRICTURE OF THE URETHRA BY MEANS OF PHYSIOLOGICAL REST.

BY F. F. BURGHARD, M.D., M.S. LOND., F.R.C.S. ENG.,
ASSISTANT SURGEON TO KING'S COLLEGE HOSPITAL.

FEW surgeons will deny that the proposal of Mr. Mansell Moullin, contained in THE LANCET of Jan. 16th, 1892, to submit cases of inveterate penile urethral stricture to a more or less prolonged period of perineal drainage with a view to secure a permanent disappearance of the stricture, is one that will require the support of the strongest possible evidence before it is likely to supplant the methods of treatment already in vogue. The results that are generally to be obtained either after the simple dilatation of a penile stricture or a combination of this with internal urethrotomy are sufficiently satisfactory to make one demand the clearest proof of the efficacy of the more severe form of treatment before one would feel inclined to recommend, or even sanction, its adoption. A careful perusal of Mr. Moullin's paper leads me to the conclusion that a sufficiently convincing case in favour of the performance of perineal section in these cases has not been made out; and I will endeavour to show, in as few words as possible, why the method by dilatation and internal urethrotomy should be preferred.

The questions at issue are two in number. First, Are the results of the usual treatment of penile urethral stricture sufficiently unsatisfactory to warrant us in recommending patients to submit themselves to the operation of perineal section and the six weeks' sojourn in bed that it entails? Secondly, if we do recommend them to submit to the operation, can we promise a definite and permanent cure, without the necessity of dilatation at some future date? Both questions I will venture, with all diffidence, to answer in the negative. My personal experience of the operation of internal urethrotomy is perhaps somewhat limited, but from the few cases I have done and several that I have seen, I am fully convinced that when once a penile stricture has either been incised or fully dilated (preferably somewhat over-dilated) it gives but little subsequent trouble, and only requires the passage of a bougie at comparatively infrequent intervals. In illustration of this may be mentioned two cases that are under my care at the present time. Both have been the subject of penile stricture. In the case of the one an internal urethrotomy was performed two years ago, and in the other the stricture was dilated up to No. 16 English some nine months since. Both these patients have attended at intervals of three months ever since, and there has been no evidence of any marked contraction taking place again; that is, there has never been the least difficulty in passing a full-sized bougie. But granting that the patient has to pass an instrument for himself for the rest of his life, there seems to be no particular inconvenience and no special danger attaching to the performance of the operation. It has only to be passed, as the cases above well illustrate, at comparatively infrequent intervals; it has only to be introduced for a certain number of inches, and need never penetrate to the bladder; consequently there is nothing much to be feared from sepsis. And lastly, the instrument being large and bulbous-ended, the patient cannot well do himself an injury. Whether a penile "stricture," divided or simply dilated, can ever become permanently absorbed, and a radical cure thus effected, there is at present no evidence to show. It is an undoubted fact that the so-called "indurations" (as detected by the bougie or the endoscope) may entirely disappear within a comparatively short time. But these "indurations" cannot be called true "strictures," and even in these cases it appears more probable that they will disappear more rapidly under the influence of the counter-irritation that the passage of large-sized instruments exerts than under that of rest alone. The cases quoted by Mr. Moullin do not, unfortunately, give any real proof that true penile strictures can be cured by the employment of physiological rest. The true test, the after-history of the cases, is not given, either because it could not be ascertained or because the cases were too recent to have any after-history. This fact encourages me to record a case which occurred to me, and which led quite erroneously to the conclusion that a penile stricture had been cured by rest alone. In September, 1890, I operated upon a labourer for extravasation of urine. He had two strictures, one four inches and the other nearly seven inches from the meatus; the penile stricture just admitted the finest catgut bougie, the deeper one was impermeable. Perineal section was performed and all the urine passed for six weeks by the perineum. At the end of that time the first attempt at catheterisation was made, when it was found that a No. 5 English catheter went through both strictures with the greatest ease, the penile one allowing the passage of a No. 7 without any difficulty. This latter was not felt at all as the dilatation of the deeper one proceeded; and when the patient was discharged the deep stricture was fully dilated, and no trace at all of the penile one could be felt. Yet after a lapse of several weeks—the patient having in the meantime broken his catheter—he presented himself once more, with the penile stricture contracted up so that it would barely admit a No. 6.

Experience of this kind leads me seriously to doubt whether rest alone can ever suffice to cure permanently an inveterate stricture of the urethra. What it undoubtedly can do, of course, is to allay spasm, to allow all congestion to subside, and to absorb, partially at least, any masses of plastic lymph that may have been thrown out either in the mucous membrane or the peri-urethral tissues, and which are usually pretty abundant in a stricture that has been exposed to much irritation.[1] Even this latter function would probably be aided by the occasional passage of a bougie. The whole question as to whether or not a case of stricture can be permanently cured by rest depends upon whether the stricture is caused merely by masses of lymph or by organised fibrous tissue. Where the latter exists—as it almost certainly must do in strictures that deserve the name "inveterate"—it seems quite hopeless to look for its entire absorption under the influence of physiological rest, however carefully it may be carried out. Rest will reduce it to its minimum by aiding the absorption of all superfluous plastic lymph, but it cannot absorb it entirely, and it will not hinder it from eventually contracting up. Take, for example, the case of a perforation left in the soft palate after an operation of staphylorrhaphy. It is well known how greatly it will undergo contraction from the cicatrisation of its circumference. It may be urged that penile strictures are not invariably cicatricial. True; but I have examined many such strictures and have always found a certain amount of definite new-formed fibrous tissue present, and I do not remember any case of stricture that I have examined where I could say that fibrous tissue was entirely absent.

It is difficult to see why, if penile strictures can be absorbed by rest and permanently cured, the same thing should not apply to the strictures that are seated deeper down the urethra. That such is not the case is sufficiently well known; the dilatation that occurs in a stricture after a prolonged drainage of the bladder through the perineum is often very considerable, and almost always occurs to some extent; but few strictures dilate sufficiently to allow anything but a medium-sized instrument to be passed, even after many weeks' rest. The first case of Wheelhouse's operation that I saw performed was done for the relief of a stricture that had remained impermeable after perineal drainage had been employed for two months. That certain cases of urethral stricture may be permanently cured by operation I have for some years believed and taught. The first case that drew my attention to the fact was met with in 1887, when I was surgical registrar to Guy's Hospital. A man presented himself for some minor ailment who had had a Syme's urethrotomy performed upon him by Mr. Howse some eighteen or nineteen months before. In answer to inquiries, he vouchsafed the information that he had discontinued the catheter three weeks after leaving the hospital, and had never had an instrument passed since. His urethra allowed the passage of a No. 12 bougie without the slightest hitch, and no trace of any stricture could be detected. Two years ago Mr. Bryant related to me the history of another case where, subsequently to the original urethrotomy and dilatation, nothing had been passed through the urethra for more than twelve months without any sign of contracting. Since then I have had two cases under my own care illustrative of the same point. The first case

[1] With a condition of more or less diffuse peri-urethritis, such as appears to have existed in one at least of Mr. Moullin's cases, rest would no doubt be efficacious in promoting absorption.

Digitized by Google

was that of an Australian gentleman, on whom I performed Wheelhouse's operation in January, 1890, but of whom I lost sight almost directly, as he returned to Australia. He had instructions to pass a large bougie once every six weeks or two months. I saw him in November last, and passed a No. 12 bougie without meeting with any trace of the stricture. He then informed me that he had lost his bougies on the voyage out to Australia, and that "he had been too busy to see about getting any more"; and that, consequently, no instrument had been passed for more than eighteen months. The second case was that of a man on whom I performed Gouley's operation for stricture in June last, at King's College Hospital. No catheter was left in; it was merely passed every six hours for the first five days, and after that the man micturated normally. No urine came through the perineal wound, which healed by first intention, and the patient left the hospital on the fourteenth day. A bougie was passed once a week for the first three weeks; then once, a month later; then again after an interval of two months; and finally four months later still. He is to have the next one passed in eight months' time. A No. 12 detects no trace of stricture. The possibility of a permanent cure of stricture after operation quite accords with what we find on examining the site of such operations after death. The incision in the strictured urethral wall is occupied by a very delicate film of cicatricial tissue which presents a marked contrast to the dense tissue of the stricture itself. It can well be understood how such a thin web can be kept permanently dilated by the urine stream. And it follows, too, from this that the reason why old dense strictures, where there is foul urine &c., relapse more rapidly after urethrotomy than do those where such changes have not taken place, is that the septic condition of the perineal wound favours the production of new connective tissue, and so replaces the divided stricture by one of new formation.

Weymouth-street, W.

ENLARGEMENT OF THE SPLEEN IN YOUNG CHILDREN.

BY J. WALTER CARR, M.D., M.R.C.P.,
PHYSICIAN TO OUT-PATIENTS, VICTORIA HOSPITAL FOR CHILDREN, CHELSEA.

As in adults so in children, enlargement of the spleen may be due to numerous and well recognised causes, some of an acute, others of a chronic character. Typhoid fever, malaria, leucocythæmia, tuberculosis, embolism, lardaceous disease, cirrhosis of the liver,—each one of these may of course produce a greater or less hypertrophy of the spleen. But whilst in very young children enlargements due to any of the above-mentioned conditions are comparatively rare, and not usually difficult of diagnosis when they do occur, there is a splenic hypertrophy found in infants, very chronic in its course, very serious in its prognosis, so frequent in its occurrence as probably to out-number all the cases of enlarged spleen due to other causes during infancy, and yet so ill defined in its etiology that it has hardly acquired a distinctive name, and in many medical works is only referred to incidentally under the heading of rickets or of syphilis. Nevertheless, its course, symptoms, and pathological anatomy appear to be so definite and characteristic as to constitute it a disease *sui generis*, and entitle it to as well-defined a place in our classification as has been assigned to the allied conditions leucocythæmia and lymph adenoma, from which however, as we shall presently see, it is easily distinguished. Perhaps the term "splenic anæmia," proposed by Griesinger, is the best to assign to it. It is necessary to distinguish a spurious from a real enlargement of the spleen in children; sometimes, without any genuine hypertrophy, it is considerably longer and thinner than natural; under such circumstances, particularly should it be pushed down by the contraction of a rachitic thorax, the lower end may be felt below the ribs, but it feels soft, not hard; there are none of the characteristic symptoms associated with genuine hypertrophy, and several times at a necropsy I have found that, though considerably elongated, the weight of such a spleen has not been abnormal or its consistence increased.

The following description of the symptoms and course of the disease is based on thirty cases observed during the last three years at the Victoria Hospital for Children, Chelsea. During that period not a single example of genuine leucocythæmia came under my observation, and the cases of enlarged spleen from all other causes (chiefly tubercular) in children under three years of age were fewer in number than those of simple splenic anæmia. Sixteen of the patients were males and fourteen females; in age they varied from two months to two years and a half when first seen. They were usually wasted, but by no means invariably so, particularly the slighter and earlier cases; but only in one or two instances were the children really plump and well developed. There was nearly always some pallor; this was extremely marked in the more severe cases, and was associated often with the more especially characteristic splenic appearance—a waxy colour with a faint olive tint, indicating almost at a glance the nature of the case. The degree of enlargement of the spleen varied; in nearly every instance it could be distinctly felt at least an inch or an inch and a half below the costal margin, and in about half the cases it extended down to the level of the anterior superior iliac spine and forwards nearly to the umbilicus. It always felt exceedingly hard, and was not usually tender. It must be remembered that in children the costo-colic fold of peritoneum is much firmer than in adults; so that in the earlier stages of splenic enlargement it directs the lower end of the organ forwards, and so prevents it from projecting as far below the ribs as it otherwise would, and perhaps causes it to encroach more on the thoracic cavity. The liver was apparently enlarged in about half the cases; but little importance can be attached to the extent of its projection below the costal margin, on account of the varying contraction of the chest by rickets, and the weight of the organ post mortem never indicated any decided hypertrophy. There was usually also swelling of some of the external lymphatic glands, but never to any marked extent; they were always hard and freely movable. In four of the fatal cases (8, 15, 16, and 30) hæmorrhages occurred—either epistaxis or small scattered purpuric spots in the skin, or both,—and Case 6, the child recently under treatment in Westminster Hospital, had profuse epistaxis shortly before admission there. These hæmorrhages probably depend solely on the severe anæmia, for, as Dr. Stephen Mackenzie pointed out in his Lettsomian Lectures on Anæmia in 1891, they may be met with whenever the proportion of red blood-corpuscles falls below 50 per cent. of the normal, a condition which obtained in all the cases referred to. In a similar way may be explained irregular attacks of moderate pyrexia, which occurred from time to time in the more severe cases whilst under observation in the wards. There was seldom an opportunity of examining the urine, but in two patients (Cases 15 and 30) a faint cloud of albumen was present, and in three others (Cases 5, 6, and 7) it was noted to be absent. According to Dr. Crozer Griffith, in Keating's Encyclopædia of Diseases of Children (vol iii., page 799), the urine in this disease does not contain albumen. The blood was examined, once or oftener, in fifteen of the children, and showed merely a condition of simple anæmia. In the most severe cases it was distinctly watery and paler than natural, and flowed very freely from a small prick. The red corpuscles always ran into rouleaux; they varied considerably in size, but presented no abnormal shape. In number they ranged from 32 to 78 per cent. of the normal; in only three instances, however, was the percentage less than 40, and two of these were fatal; the general range was from 45 to 70 per cent.; and even this may give somewhat too low an average, as in several cases in which the blood was not examined the anæmia was not at all profound. In one infant (Case 8) the number of red discs fell in eleven weeks from 64 per cent. to 37 per cent., then under treatment with reduced iron rose again to 63 per cent., when the patient died of diphtheria. In another instance (Case 20) which steadily improved the percentage rose from 62 to 82·6. The percentage of hæmoglobin was ascertained in seven of the cases, and was not found to bear any definite relationship to the number of red corpuscles; in all, however, as in simple anæmia and chlorosis, and in contrast with pernicious anæmia, it was deficient, both actually and also relatively, to the number of corpuscles. The hæmoglobin value of the individual corpuscle was usually from 50 to 67 per cent., but in one case (19) in which the percentage of red discs was 78, two estimations of the hæmoglobin gave only 25 and 28 per cent. respectively. From the few cases in which several estimations were made the increase or decrease of

Digitized by Google

hæmoglobin seemed roughly to vary *pari passu* with that of the red corpuscles. It is perhaps doubtful whether the results of examination of the blood with the hæmoglobinometer are very reliable in childhood, and I shall be glad to hear the opinions of others on this point. In nearly every instance there was a slight excess of white corpuscles, but this was not marked, especially when we remember that in young children they are normally somewhat more numerous relatively than in adults—in infants, 1 white to from 130 to 210 red corpuscles. In only one instance (Case 8) did the percentage of white discs approach the leucocythæmic condition, and that was after epistaxis, when the red corpuscles fell to 37 per cent, with 1 white to 33 red ones. In this case all the lymphatic glands, both internal and external, were enlarged, though none were bigger than a small filbert: even the Peyer's patches and solitary glands of the intestine were found distinctly swollen. In the other cases there was 1 white to from 70 to 225 red discs, averaging about 1 to 100, so that it is quite evident that this disease is distinct from leucocythæmia.

It is well known that anæmia is often a prominent symptom of rickets, and, as nearly all these children were rickety, the question naturally arises whether the blood changes described were dependent mainly or even entirely upon the rickets. It seems to me, however, that, at any rate in the marked cases, the anæmia was always more profound than could be explained by the rickets alone, and, more particularly, that the diminution of red corpuscles does not occur to such an extent in simple rickets. Thus, in one case of well-marked rickets and anæmia, I found 98 per cent. of red discs and only 28 per cent. of hæmoglobin, and in twins with marked rickets and pallor the percentage of red corpuscles in each was about 80 and of hæmoglobin 70. As I have already stated, in none of my cases of splenic enlargement did the percentage of red discs exceed 78. Moreover, in the blood of cases of simple rickets there does not seem to be the same tendency to even a slight excess of white corpuscles.

The course of the disease is essentially chronic, and so it is difficult in out-patient practice to trace the cases to their termination. In some instances the splenic enlargement and the anæmia steadily increase, hæmorrhages occur, and the child dies at last from exhaustion, usually complicated by more or less catarrh of the mucous membranes, leading to bronchitis and broncho-pneumonia, or to diarrhœa. Ten of my thirty cases are known to have died mainly in the way just mentioned; but this is, perhaps, a higher mortality than that of a number of cases taken indiscriminately, as the thirty cases include an undue proportion treated as in-patients on account of their specially severe symptoms. Six of the cases could not be traced, of the remainder thirteen were found either to have completely recovered or to be steadily improving; Case 6 alone remained *in statu quo*. In Case 3, after only four months of treatment, the child's general condition and colour were greatly improved and the spleen could scarcely be felt, but this was a slight case from the first, and the spleen was never much enlarged. In Case 10, examined after a year and eight months, the spleen could not be felt, and the red discs had risen from 42 per cent. to 104 per cent. In Case 19, after eight months, although the spleen was still enlarged, the red corpuscles had risen from 78 per cent. to 98 per cent., and the hæmoglobin from 26 per cent. to 45 per cent. In Case 20 the spleen at first reached to the level of the anterior superior iliac spine, and the anterior border was in the nipple line; the lower border of the liver was felt half way between the umbilicus and the ribs; the inguinal glands were enlarged. Five months later the child was stouter and of better colour, the spleen could not be felt, the liver only projected an inch below the costal margin, and there was no glandular enlargement. From the first, however, the anæmia in this case was not extreme—viz., red discs 62 per cent., hæmoglobin 45 per cent.; the former rose to 82·5 per cent., the latter remaining about the same. In Case 22 the spleen was nearly as large as in the one just described; after three months it only reached an inch below the ribs, and there was much improvement in the child's colour and nutrition; it unfortunately succumbed to an attack of whooping-cough. Occasionally there seems to be no definite change after several months of treatment; Case 6 shows this especially, as after two years the child's condition was almost unaltered, the anæmia much the same, and the spleen a little larger.

The prognosis of cases of splenic anæmia as given by different writers varies immensely. Crozer Griffith, in Keating's Encyclopædia, says that permanent cures are of the rarest occurrence unless the splenic enlargement be due to syphilis or malaria; Henoch says that most of the children die from progressing anæmia, wasting, and, finally, dropsy of the cavities; Eustace Smith, on the other hand, gives a much more favourable prognosis; whilst Ashby and Wright state that most of the cases improve after a while, but that their course is very chronic. From my own observations I should say that the prognosis in these cases is not necessarily bad, though the disease will probably be of long duration; but should the spleen get very large and the anæmia profound, there is of course great danger of death from simple asthenia, from pulmonary trouble, or from the onset of any acute specific disease, which will probably prove rapidly fatal in a child already greatly weakened. Although the prognosis is usually more unfavourable the greater the enlargement of the spleen, yet it is interesting to note that in Case 4, in which the child steadily got worse and had marked anæmia, the organ was only slightly enlarged, weighing one ounce. Later on I shall mention facts which seem to point to the presence of well-marked syphilitic manifestations being a particularly unfavourable indication.

Morbid anatomy.—A necropsy was obtained in seven (Cases 4, 8, 15, 16, 26, 27, and 30) of the ten fatal cases. In all there were great emaciation and pallor of the internal organs, in four marked bronchitis or broncho-pneumonia. Case 4 was the only one in which there was any sign of tubercle, in this case there was a mass of caseous mesenteric glands. The liver was but slightly, if at all, enlarged in any instance, its greatest weight being fifteen ounces and a half. In appearance it was either normal or paler than natural; in only two of the cases (4 and 26) was it notably tougher than usual, and in two others (8 and 15) the consistence was very slightly increased. In one case (8) there was a depressed scar-like patch in the liver, perhaps the remains of a gumma; this was the only indication of visceral syphilis found in any examination. We may conclude, then, that the changes which the liver undergoes in these cases are unimportant, and that its enlargement is apparent rather than real, being due either to the relatively larger size of the liver in infancy or to the contraction of a rachitic thorax.

As regards the internal lymphatic glands, in no case was there any swelling of those in the thorax beyond what would be attributable to bronchitis or broncho-pneumonia. In four cases the mesenteric glands were normal; in one case, as already mentioned, caseous; and in two (Cases 8 and 16) slightly swollen. The bone marrow I have not examined, but it is said that that of the long bones may present in some cases the same dark-red lymphoid appearance frequently seen in pernicious anæmia.[1] In two cases the spleen was slightly adherent to the surrounding parts, and in a third there were a few flakes of lymph on the surface, but in no instance was there any distinct thickening of the capsule. In one case (4) the organ was but slightly enlarged, weighing 1 oz.; in the others it varied from 4 oz to 8½ oz. in weight. In all it was firm, and the consistence was distinctly increased; the section was dark and fleshy, but otherwise fairly natural in appearance, with no enlargement of the Malpighian corpuscles. Iodine solution gave no albuminoid reaction. None of the other organs presented any noteworthy change. The microscope confirmed the naked-eye appearance of the spleen by showing that the enlargement was apparently due to a simple hypertrophy, with more or less increase of fibrous tissue. In one case (8) there were scattered patches having somewhat the aspect of albuminoid change, a condition probably identical with the hyaline fibrosis which Cheadle has described.[2] The microscope showed no important changes in the liver or lymphatic glands, but in some instances there seemed to be slight overgrowth of connective tissue in the kidneys. The appearances presented by the spleen seemed to be the same whether the enlargement were associated with syphilis, with rickets, or with neither of these diseases; it also resembles the ague spleen. The condition described corresponds with the descriptions given by other writers, especially by Henoch and by Ashby and Wright; but I cannot be sure whether Jenner refers to a similar condition, when in his lectures on Rickets he speaks of an albuminoid infiltration of the spleen, with some simi-

[1] Dr. Crozer Griffith's article on "Splenic Anæmia," in Keating's Encyclopædia of Diseases of Children.

[2] Brit. Med. Jour., ii. 1888, p. 1148.

Digitized by Google

lar affection of the liver and lymphatic glands, leading to enlargement of all these organs, and causing the emaciation seen in some cases of rickets. He describes the spleen as non-adherent, capsule scarcely if at all thickened, the substance of the organ tough but elastic, pale-red or dark-purple in colour; liver usually only slightly enlarged, heavy, tough, and semi-transparent; external lymphatic glands enlarged, not tender, and never inflamed. Although he speaks of an albuminoid infiltration of all these organs, he says that it has not the characters of the albuminoid change described by Virchow, and especially that it does not give any reaction with iodine solution. On the whole, from the general symptoms and accompanying conditions of these cases, it seems probable that the so-called albuminoid infiltration of the spleen associated by Jenner with certain cases of rickets is identical with the condition which I have been describing.

(To be concluded.)

A NOTE ON REID'S UTERINE DILATORS.

BY JAMES BRAITHWAITE, M.D. LOND.,
OBSTETRIC PHYSICIAN TO THE LEEDS GENERAL INFIRMARY.

IN 1888 Dr. Reid of Glasgow brought under the notice of the profession his uterine dilators. These consist of five conical dilators about two inches in length, which fit on a handle or stem common to all. The smallest of these dilators is a quarter of an inch in diameter at its narrow end, and three-eighths of an inch at its widest or proximal end. The largest is one inch in diameter at its widest part. The principle of action is that of a screw wedge. All the dilators have on the surface a shallow blunt screw, so made as not to cut the mucous membrane of the cervical canal of the uterus when introduced by a rotatory movement, but at the same time sufficiently deep to retain a hold on the parts through which they pass. When the British Medical Association met in Glasgow in 1888 I saw these dilators and procured a set from the makers, Messrs. Hilliard and Sons of Glasgow. They have served me in such good stead since in cases in which nothing else would have done that I propose to give two or three examples of their utility, especially as I have never since seen them mentioned in any way in the current medical literature of the day, and their value seems to be not known or appreciated.

In April, 1890, I saw with Dr. Thompson of Great Ouseburn a lady who was in such a condition from pregnancy vomiting that it was necessary to empty the uterus of a two months' fœtus in order to save her life if possible. The cervix was extremely rigid. I dilated first by Hegar's dilators, but could only get to size 9. By no justifiable force could any larger size be got in; so I then inserted a large laminaria tent, not having Reid's dilators with me. Next day I again tried with Hegar's; but I only got in two sizes larger. I now used Reid's, which I had meanwhile procured, and dilated at once to the fourth size; so that the left index finger passed through the cervix, and I completely emptied the uterus of a quantity of semi-putrid secundines by means of Gervis's ovum forceps, but no fœtus was found. The patient rallied for a day or so, but soon sank, the vomiting continuing. For three weeks previously the stomach had retained no food whatever, so this result was almost to be expected. The point, however, in the case is the ease with which Reid's dilators acted after the failure of Hegar's.

In October last I had a similar case, but more urgent still, and without these instruments I believe a successful termination of the case would have been impossible. A gentleman married a lady in California. Within a short time she became pregnant, and incessant vomiting necessitated the induction of abortion. She recovered from this, and became pregnant for the second time, but there was no vomiting, and she was delivered of a healthy male child at full term. She was attended by Drs. Ellerton and Clayton of Aberford, near Leeds, for she came to England to her husband's home. Becoming pregnant for the third time, vomiting came on at once; and when I saw her with her medical attendants named, she appeared to be within two days of her death, the stomach having retained no food for fourteen days. There was no time to wait for anything; the uterus had to be emptied at once. The cervix was closed firmly and felt somewhat hard. I dilated it to the fourth size of Reid's dilator. This took about an hour, as plenty of time should be given in the use of such a powerful instrument. The uterus was then emptied by means of Gervis's ovum forceps. This was upon a Wednesday; the vomiting abated considerably on the Thursday and ceased on the Friday, and the patient then recovered. I had a letter a week afterwards giving these particulars. I believe that no other dilator could have accomplished this, for great power was required; and the upward pressure necessary to introduce Hegar's instruments, one after the other, would have caused the vulsellum with which the uterus must be held to tear out. We have used this instrument extensively in the infirmary wards in the treatment of dysmenorrhœa. I will give one case of dysmenorrhœa, a private one, however, in illustration of its use in this disease.

A lady, thirty-four years of age, and unmarried, had suffered from dysmenorrhœa since she was eighteen, apparently induced by over-exertion in walking. It has become much more severe the last few years, and she had derived no benefit from the treatment of the physician who usually attended the family. In February, 1890, I dilated the cervix with Hegar's dilators to size 6 or 7, and inserted a large laminaria tent for the night. On withdrawing this next morning I did nothing further, as the parts were fairly but moderately dilated, and she had taken the ether necessary so badly that I did not like to give it again. No benefit whatever followed this dilatation except for the first time following. In May, 1891, I again dilated and used the tent as before; but on the second morning dilated with Reid's dilator to size 4, not passing it quite up to the full length. This has so far proved an absolute cure. I saw her a few days ago, and she has been as nearly as possible free from pain and is in good health, whereas she was previously almost a chronic invalid.

I could give many other illustrations, but those given show, I think, the great value of Reid's dilators. In use they simply require oiling and then passing into the cervical canal. The small end of the wedge is quite rounded and smooth. The handle is then rotated and the wedge screws itself in, dilating very gradually, but with immense power. I have never used the largest size, as the fourth one allows of the index finger passing, and I believe the largest size too large for an unimpregnated uterus, and possibly involving risk of laceration. It is necessary to steady the cervix by a vulsellum, or hook, but there is no risk of this tearing out or lacerating the tissues, as I have several times seen when Hegar's are used, for there is no upward dragging. Since this paper was written I have had a patient almost dying from hæmorrhage from what was supposed to be a sloughing fibroid. The cervix was contracted and did not admit the finger, and was woody and hard. It was dilated to the largest size with Reid's dilator, and as much as could be reached of the tumour removed. I thought at the time that it was all removed. The patient died within twenty-four hours from, as the necropsy showed, a large abscess full of offensive pus, but the cervical mucous membrane showed no trace of the action of the screw dilator, and it was examined very carefully in a good light.

I hope these cases may lead to a more general use and appreciation of the instrument, for which the thanks of the profession are due to Dr. Reid.

Leeds.

RELATION OF INFLUENZA TO CLIMATIC CONDITIONS AND TO ZYMOTIC AND RESPIRATORY DISEASES.

BY C. ROBERTS, F.R.C.S. ENG.

THE borough of Nottingham has issued an admirable coloured chart and a series of meteorological tables illustrating the relation of the number of deaths from various causes to the principal meteorological conditions on each day of the year 1891, but without any comments. As there was an epidemic of influenza during the ten weeks from April 22nd to June 30th, the chart affords an opportunity of studying the relation of this disease to climatic conditions and the prevalence of other diseases, independently of all

Digitized by Google

preconceived ideas. The chart and tables do the compilers great credit, and their example might be followed with great advantage by other corporations. The meteorological curves do not throw much light on the cause and spread of the influenza. There was a high barometer, with a low and narrow range of temperature and a corresponding rainless and sunless condition, during the seven weeks preceding the outbreak of influenza. During its prevalence there was nothing remarkable in the climatic conditions, except an extreme range of temperature from a maximum of 72° to a minimum of 29°, equal to 43°, from May 13th to 18th, the period of the maximum death-rate from influenza and respiratory diseases. There were corresponding variations in the sunshine, the days of high temperature being very sunny, and those of low temperature sunless. There were ten days with hardly any sunshine at a period when sunshine is most plentiful in this country. There was nothing exceptional in the atmospheric pressure, rainfall, or direction of the wind during the ten weeks in which deaths from influenza were recorded.

When we examine the columns representing the number of deaths from various causes, we come on the remarkable facts that influenza usurps to a large extent the place of the zymotic diseases, and anticipates to a great extent the lethal effects of other diseases. The deaths from zymotic disease fall from 101 in the ten weeks before the influenza to 77 during the ten weeks of its prevalence, and to 31 in the ten weeks after it has disappeared. The deaths from respiratory diseases, which were 191 in the first period, rose to 262 during the epidemic, and fell to 78 during the ten weeks following it. The variations of deaths of persons above sixty years follow the course of the respiratory diseases; there were 234 in the first period, 302 in the influenza period, and 147 in the subsequent period of ten weeks. The following table shows at a glance these fluctuations in the deaths. As the epidemic occupied ten weeks I have arranged the other periods in groups of ten weeks each. The influenza period forms the centre group. The population of Nottingham in 1891 was 212,662, and the death-rate during the year 19·3 per 100.

	Deaths from zymotic diseases.	Deaths from respiratory diseases.	Deaths above 60, from all causes.
Ten weeks preceding the influenza, from Feb. 12th to April 23rd	101	191	234
Ten weeks of epidemic influenza, from April 23rd to June 1st. (Zymotic 77, influenza 100)	177	262	302
Ten weeks following the influenza, from June 2nd to Aug. 9th	31	78	147
Average	103	177	228

From these figures we see that influenza has, as it were, picked out the bad lives from the subsequent period, for if we average the deaths of the influenza and subsequent period we obtain the numbers 104 for zymotic and influenza, 170 for respiratory diseases, and 224 for deaths above sixty years of age, values which give only 3 zymotic deaths in excess of the pre-influenza period, and 21 respiratory and 10 old-age deaths less than that period. Some allowance must be made for the lower death-rate of the summer than the spring months; but, making ample allowance for this, it is obvious that the 100 deaths attributed to influenza were not an addition to, or excess of, the normal death-rate, but a mere variation of the name and time of registration of the deaths; and Nottingham as a community lost nothing (except a few weeks' labour) by the invasion of the epidemic of influenza in 1891. If further observation bears out these results there should be little reason for the panic which is spreading everywhere. May it not also help us to new views of the pathology of influenza when we find it supplanting zymotic diseases? My object is not, however, to discuss the pathology of influenza, but to call attention to its incidence, and its relation to other diseases and to the public health, as shown by the admirable chart issued by the Nottingham sanitary authorities, but which has been left for each student of vital statistics to interpret in his own way.

Curzon-street, Mayfair, W.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

LITHOTRITY IN CHILDREN.

BY F. A. SOUTHAM, M.B. OXON., F.R.C.S.,
SURGEON TO THE MANCHESTER ROYAL INFIRMARY AND TO THE CLINICAL HOSPITAL FOR WOMEN AND CHILDREN.

IN THE LANCET of Feb. 15th, 1890, I published a case of lithotrity at a single sitting in a boy aged three years and a half, and since that date I have performed the same operation in five additional cases, brief particulars of which are here given:—

Case.	Age.	Size of stone.	Structure.	Weight.	Duration of operation.	Result.
	Years.	Inches.		Grains.	Min.	
1	3½	Oval: ½	Uric acid	15	25	Up on 3rd day, discharged on 7th.
2	10	½ × ¾	,, ,,	45	70	Up on 5th day, discharged on 21st.
3	4	½ × ½	,, ,,	14	30	Up on 4th day, discharged on 7th.
4	5	1½ × 1	,, ,,	125	60	Up on 3rd day, discharged on 8th.
5	5	Oval: ⅝	,, ,,	13	20	Up on 2nd day, discharged on 8th.
6	3	,, ⅞	,, ,,	32	45	Up on 4th day, discharged on 7th.

In each instance the result has been extremely satisfactory, confirming in every respect the Indian experiences of Surgeon-Majors Keegan and Freyer, who were the first to advocate and practice this method of treating stone in male children. In performing lithotrity in young subjects, one is surprised to find how extremely tolerant the bladder is of prolonged instrumentation, the essentials for success being, in the words of Surgeon-Major Keegan, "great gentleness and a light hand." With two or three ounces of fluid (boric lotion) in the bladder, and the pelvis and thighs of the patient slightly raised so that the stone may fall back upon its posterior wall, the operation is a very simple one; in fact, much easier of performance than in an adult, the absence of any pouch or depression behind the prostate facilitating the seizure of the calculus and the removal of the fragments after it has been crushed.

Before deciding upon lithotrity in a child, it is, I think, advisable to know the exact size of the stone. This can be best estimated by measuring it with a small lithotrite when the child is sounded; more satisfactorily of course if the examination is made under anæthesia. As cystitis is usually present to a greater or less extent, the bladder should at the same time—viz., while the patient is under the influence of the anæsthetic—be thoroughly washed out with boric lotion. For a few days previously to the operation the irrigation should be repeated each morning, an anæsthetic not being necessary. By this means the condition of the urine is improved, the cystitis is relieved, and the urethra becomes accustomed to the passage of instruments. If a soft indiarubber catheter is used for the purpose, it causes scarcely any pain, and is usually well tolerated by the patient. In cases where the urine is very offensive—as happened in Case 2—small doses of boric acid may also be given internally. In none of my patients has it been found necessary to continue the irrigation after the operation, the removal of the calculus having been followed by a subsidence of the symptoms of cystitis. I am of opinion that by the employment of what we may term "urinary antiseptics"—namely, drugs such as boric acid, salol, &c., by means of which we are able to sterilise foul or toxic urine, and at the same time relieve inflammation of the bladder walls—the risks and after-complications of lithotrity in children, as well as in adults, are greatly minimised. As the operation is often somewhat prolonged, it is very important to guard against exposure to cold, and also to diminish as far as

Digitized by Google

possible the effects of shock. With this object I always take care that the body and limbs of the child are wrapped in flannel bandages, and during the operation the patient lies upon a large, flat, hot-water tin, covered over with a blanket, which fits on the operating table. If hot fomentations are applied to the lower part of the abdomen and perineum after the operation, the child will usually pass urine in the course of a few hours without any straining or difficulty, and, beyond a slight smarting, with very little pain, usually much less than previously to its performance. In only one of my cases has there been any rise of temperature, and the following morning the patients have all been practically convalescent. It is, however, advisable to keep them in bed till the third or fourth day, when they may sit up in the ward, and at the end of a week they are usually quite fit to leave the hospital. In each instance the operation was performed with Weiss's Nos. 5 and 7 children's lithotrites, and the fragments removed with Nos. 6 or 8 evacuating tubes. In Case 4, as the stone was too large to be crushed with No. 7 lithotrite, it was first broken up with one of Weiss's small lithotrites for adults (about No. 9 size), and the operation was completed with Nos. 5 and 7 lithotrites. This case illustrates the fact that a calculus of considerable size—viz., over an inch in diameter—may be safely crushed in a young child. I believe that in the future lithotrity will quite supersede lateral lithotomy in children, and also that if a stone is too large to be crushed, it will be an indication for the selection of the supra-pubic operation.

Manchester.

A CASE OF HEMICHOREA FOLLOWED BY PARALYSIS (PARTIAL HEMIPLEGIA) IN A CHILD FOUR YEARS OF AGE.

BY E. A. PIGGOTT, L.R.C.P. & S. EDIN., L.S.A. LOND.

THE following case is of interest not only as occurring in so young a child, but also as exemplifying the embolic theory in the causation of chorea. The partial hemiplegia, I take it, as clearly indicating cerebral breach of structure, in all probability dependent upon capillary embolism. For the early history of the case I am indebted to the parents of the child, at which period she was under the care of another practitioner. The case came under my observation only a short time before the development of the hemiplegic symptoms. M. D——, aged four years, the child of healthy parents, suffered more or less from convulsions during dentition, the commencement of which was delayed until she had attained the age of eighteen months. When she had completed her fourth year she was attacked with influenza, which was generally epidemic at the time (March, 1890). During the interval of time between the subsidence of the convulsions synchronous with dentition and the attack of influenza the child enjoyed perfect health. The attack of influenza was succeeded by marked choreic movements in the left upper extremity, the facial muscles on the left side being the next affected; the disease, assuming a decidedly progressive character, ultimately reached the left lower extremity. The muscular contortions were almost entirely limited to the left side of the body, and were often present during sleep, frequently causing the little patient to awake with a sudden start. Locomotion was also interfered with, the left leg being drawn along the ground in walking. A nourishing diet, consisting of milk, beef-tea, eggs, &c., was ordered, and a mixture containing compound syrup of the hypophosphites, combined with small doses of liquor arsenicalis, together with cod-liver oil, prescribed. Under this treatment there was a marked improvement in the choreic symptoms; the improvement, however, was of brief duration. Decided evidence of hemiplegia soon commenced to manifest itself, paralysis of the left facial muscles, partial ptosis, and considerable photophobia, with loss of power in the left arm to such an extent that there was complete inability to grasp any object, the child using the right hand to endeavour to assist the left, finally being unable to lift the arm at all. The bowels were relieved naturally until this date (Oct. 13th, 1890). On Oct. 15th I was called to see the patient, as the symptoms were alarming. On arrival I found the following condition—viz, pupils unequal, left dilated, right contracted; the conjunctiva of the left eye totally insensitive, with diminished sensibility in right conjunctiva; marked trismus, the jaws being firmly closed. Tonic contraction of the extensor muscles of the left arm and forearm and both legs, the left being the most complete. Temperature in axilla 100°; pulse about 120, weak; respiration normal; child groaning slightly at intervals, and moving the head from side to side. A small quantity of liquid nourishment was administered by forcibly separating the jaws. During the progress of the disease, especially after the paralytic symptoms developed, the child was constantly complaining of pain in the head, and would cry out suddenly, frequently awaking from sleep with a scream.—Oct. 16th: The condition to-day nearly approached that of complete coma. Temperature normal; muscular jerkings almost continuous in the left upper extremity, which remained rigidly extended. The fingers were clenched, and the hand drawn back to such an extent that it almost resembled in appearance a complete dislocation at the wrist-joint, both feet being similarly affected, and simulating the condition represented in a case of talipes equino-varus. The bowels were obstinately confined, the urine being passed involuntarily. From this date the patient gradually passed into a state of profound coma, sordes forming upon the lips, with a total inability to take nourishment, death finally releasing the little sufferer on Oct. 23rd. A post-mortem examination was not permissible.

The foregoing case, in a great many of its details, resembles tubercular meningitis. Both parents being young and vigorous, there was no reason for supposing the child directly inherited a tuberculous diathesis; doubtless a tendency to brain mischief existed, owing to the convulsions attendant upon dentition. It is also a question what share, if any, the attack of influenza had in the production of the fatal cerebral symptoms.

Clare, Suffolk.

ATRESIA ANI.

BY JOHN K. MURRAY, M.B. EDIN.

A WELL-DEVELOPED child three weeks old was brought to me in September, 1891. I found a dimple marking the usual site of the anus, and the fæces passed per vaginam. On passing a probe the fistulous communication could not be found. Under ether, administered by my friend, Dr. Batchelor of Queen's Town, I cut down on the normal site of the anus, dividing the tissues in the middle line to the depth of an inch and a half. I could find no rectal cul-de-sac. The depth of the wound precluded further dissection. To get freer access I partially divided the posterior vaginal wall, and having passed a probe into the posterior fornix vaginæ I at last succeeded in making it enter the bowel. By inserting my forefinger into the wound I found the point of the probe just a little behind the vaginal wall. I accordingly cut down on it. This was followed by a free gush of fæces. I put a stitch in the site of the recto vaginal septum and closed the vaginal opening by absorbent wool. A bulbous silk catheter was tied in the rectum. The wound was syringed daily. By the third day no fæces escaped per vaginam. The catheter was removed, and passed into the bowel four times daily. When seen in the early part of March, 1892, it was found that a well-formed anus was present, rather nearer the vagina than in the normal perineum. No fæces have escaped since the third day per vaginam.

In this case the dimple marked the arrested deepening of the epiblastic fold which grows into and becomes continuous with the mesenteron. The high site of the rectal cul-de-sac probably indicates a defect in the development of the mesenteron itself. As regards the operation, the main difficulty was in striking the cul-de-sac, which was not distended by fæces, free egress being afforded by the vagina frequently during the operation. It is recommended by Dieffenbach and Barton[1] that, if possible, the cul-de-sac should be detached from the vagina and stitched to the skin. This may be feasible where the cul-de-sac is blind or where it comes low down, but where the cul-de-sac terminates at its communication high up in the fornix vaginæ such a proceeding is difficult, even hazardous. The result in this case shows the tendency of nature to revert to normal channels when such are re-established. The line of

[1] Medical Recorder, vol. vii., p. 357.

Digitized by Google

force was in the direction of the wound when defecation took place, consequently the healing of the trench-shaped wound formed a natural prolongation of the rectum ending at the skin.

Whittlesea, Cape Colony.

DIFFUSE HÆMATOMA OF THE BACK; DEATH.

BY G. OSCAR JACOBSEN, M.R.C.S., L.R.C.P. LOND.

I WAS called on March 18th to see T. E——, who, I was informed, had on the previous night hurt his back in a fall. On arriving I found that the patient, a man aged fifty-eight, seemed to be in considerable pain, and on examination of the back discovered a large swelling, which corresponded roughly in site and size to the right scapula. The tumour appeared to be fluid, as there were distinct evidences of fluctuation. There was no discolouration of the skin. From the history I took it to be a hæmatoma, and prescribed a lead lotion, rest, and sedatives. I was unable to obtain ice. The patient, I was told, had got up from the sofa, and was crossing the room, and during the momentary absence of his wife was seized with an attack of giddiness, and had fallen with all his weight with the right side of his back against the sharp jamb of the door-post. I had been attending him for kidney disease, and what I took to be Ménière's disease, the patient complaining of constant attacks of vertigo associated with one-sided deafness. The next day, the 19th, the man seemed no worse, but the swelling had increased. The third day he seemed in a good deal more pain, and the swelling now extended upwards under the muscles of the right side of the neck nearly as high as the mastoid process, downwards to the small of the back, and had, moreover, now become very much discoloured. The next night I was sent for again, and found the patient in a very bad way, delirious, with running pulse and great dyspnœa—in fact, moribund, and he died the next morning, the 23rd, at 5 A.M., a little over five days from the time of the accident. A necropsy was ordered by the coroner, which I made about thirty hours after death. On inspection there was found to be considerable swelling on the right side from the mastoid process to the lumbar region. This was distinctly fluctuating, and there was very great discolouration of the skin, not due to post-mortem changes. On opening the chest the first thing noticed was infiltration of all the pectoral muscles of the right side with blood. On dissecting them carefully back this was found to become more and more intense, and after reaching a point just behind the mid-axillary line there was found underneath the latissimus dorsi a huge cavity which contained over three pints of semi-fluid and coagulated blood. The intercostal muscles were sodden with blood, and at one point seemed breaking down into the pleural cavity. The right pleural cavity contained a fair quantity of blood-stained fluid, and towards the base some very recent lymph, which also was found on the surface of the base of the lung. The lungs appeared healthy, and the other organs appeared fairly healthy, with the exception of the liver, which was somewhat enlarged, and the kidneys, which were granular, with diminished cortex, and the capsule very adherent. There was atheroma of the aorta and thickening of the aortic valves.

This case I think interesting and worthy of record, owing to the comparatively slight injury—namely, the fall against the door-post—the large amount of blood effused, and the considerable length of time elapsing before death. The extent of the hæmorrhage I attributed to the brittle state of the arteries consequent upon the patient's kidney disease.

Ashwell, near Baldock.

FOOT-AND-MOUTH DISEASE IN KENT.—The foot-and-mouth disease in the Sittingbourne district is, it is stated, increasing, and threatens to become epidemic. The third outbreak in the course of a few days was reported on the 16th inst., when it was discovered that the malady had made its appearance among a flock of about 150 sheep on Oakwood Farm, near Sittingbourne, belonging to Mr. G. H. Dean. This latest outbreak has had the effect of extending the boundary of the infected district. This was apparent on Good Friday, when a large number of pedestrians who attempted to pass through Gore Court Park found several of the footpaths closed to the public and guarded by police.

WESTMINSTER HOSPITAL.

ENTERIC FEVER; RIGHT HEMIPLEGIA WITH APHASIA; RELAPSE; DEATH.

(Under the care of Dr. DONKIN.)

THIS case is placed on record on account of the exceptional occurrence of hemiplegia in connexion with enteric fever. In connexion with this case Dr. Donkin observed that some few cases have been reported, but mostly without necropsies. Two cases in children with recovery were recorded by Dr. Gee and Dr. Cayley respectively in the *Medical Times and Gazette* for 1878, vol. i. The blocking of the cerebral arteries is usually put down, according to inference from probability, to an embolic cause, and where no cardiac abnormality is demonstrated or indicated the embolism is supposed to arise from a broken-up thrombus in the left heart. In this case there was nothing noteworthy in the heart's structure or contents. We have probably to choose between thrombosis *in situ* or some temporary clotting in the heart's cavities leading to embolism for explanation of the arterial blocking which was discovered both in the brain and the lung. It seems much more probable that both the clots found were produced *in situ*, and that their cause was the same—viz., depression of the circulatory force from the long and severe pyrexia, which was evidenced by continuous dicrotism of the pulse and great weakening or silence of the first sound of the heart. Direct impairment of the nutrition of the arteries was a part of the profound effect of continued and especially of enteric fever on the tissues generally, and morbid changes in the blood were probably important co-factors with the weakened heart in producing the result. It must be remembered that the patient had an extensive bronchitis with much dyspnœa, causing excessive stress on a heart already overworked and probably dilated in the course of the fever. In this context Dr. Donkin called attention to a case recorded by Dr. J. Abercrombie where sudden left hemiplegia occurred in a boy of six years old with diphtheria, the necropsy showing thrombosis of the right middle cerebral artery without valvular heart disease or evidence of embolism. The account of the case is abstracted from notes furnished by Mr. Gossage, house physician.

The subject of this record, aged thirty, had been nursing two cases of enteric fever in a house where the drains were believed to be very defective. One of these cases died after a severe course of the fever with profuse fetid diarrhœa. The nurse began to feel ill while at her duties a fortnight before admission to hospital on Dec. 2nd. On Nov. 28th she had severe headache, and on the following two days suffered from pains all over, and shivered repeatedly. On Dec. 2nd there were slight cough, slight diarrhœa, and some vomiting. She was the subject of chronically enlarged glands in the neck, which had been getting larger during the three weeks before admission; had had "strumous conjunctivitis" two years before; and attacks of influenza in January, 1890, and May, 1891, the last being severe. On admission, the temperature was 104° F., and there was some distension, with great pain and tenderness of the abdomen. From this date to the 15th the temperature ranged between 104·8° and 102°, being usually over 103°, and there was much abdominal pain, occasional vomiting, and abundant eruption. After five days' constipation, a simple enema was given on the 8th, and subsequently there were from one to three semi-solid or solid motions on most days till the 15th, when fairly marked morning remissions of temperature set in. On the 15th bronchitic signs were heard all over the chest. The bronchitis became severe, with considerable dyspnœa, for several days, and the temperature ranged generally between 101·5° and 103°, occa-

Digitized by Google

sionally rising to 104°, until the 22nd. After this the temperature gradually fell and the bronchitis decreased, until at the end of the month pyrexia ceased and the signs of bronchitis disappeared. On the 31st the patient complained of somewhat severe pain in the head. Her bowels had not acted for several days, and an enema was ordered on Jan. 1st. The nurse, who was about to administer the enema at 6 P.M., found the patient with much impaired consciousness and unable to articulate; she had been apparently asleep for an hour previously. On examination there was drooping of the left eyelid and considerable paralysis of the right arm and leg. She could hear well and apparently understood what was said to her, putting out her tongue—which was seemingly protruded straight—very slowly. Swallowing was somewhat difficult, and urine was passed in bed. During the next few days the paralysis became complete, and there was considerable loss of sensibility in the affected limbs; the breathing was somewhat laboured, and urine and fæces were passed in bed. On the 4th the temperature rose slightly; on the 5th it was 102° in the evening; on the 8th there were rose spots, loose motions, and some vomiting. The eruption and diarrhœa continued, and on the 14th the evening temperature was 104°, the pulse rose to 160, and the breathing became frequent and very laboured. On the 15th the pulse was running, the temperature rose to 105°, and the patient died at midnight.

The necropsy was made forty hours after death by Dr. Hebb. The brain substance was pallid, the sulci deep. The left carotid was distended with a softish dark clot which extended to its principal branches, the middle cerebral being apparently most affected, but the clot was confined to the Sylvian fissure. (Owing to certain conditions of the post-mortem examination the lower part of the carotid was not examined.) The supply area of the middle cerebral was extremely disorganised, the softened parts being the left corpus striatum, the island of Reil, the operculum, the anterior fourth of the upper internal temporo-sphenoidal convolution, and the wall of the lateral ventricle in more than its front third. The corpus striatum was of a greenish-yellow hue, and only kept in position by its attachment posteriorly to the optic thalamus. Elsewhere the surrounding nerve tissue was broken down flocculent detritus. This disorganisation affected the whole of the anterior cornu and the wall of the ventricle as far back as the front of the optic thalamus. The optic thalamus was somewhat softer than normal, and chiefly affected in its outer front part. The rest of the cerebrum, the cerebellar pons, and medulla were, except that the puncta vasculosa were large, not noteworthy. The vessels of the pia mater were to the naked eye normal. The pleura was smooth. The bases of both lungs were much congested and very friable. About the centre of the anterior edge of the left lower lobe was a faintly yellow infarct, about the size of a large walnut, having somewhat the appearance and consistence of grey hepatisation. The pulmonary arteriole supplying this was thrombosed by a dark, softish clot. There was evidence of general bronchitis. The heart and peritoneum were normal. The mesenteric glands were very large and soft, and much blood-stained. The spleen was large, tense, and turgid; parenchyma very soft and quite black. Extensive "typhoid" ulceration was found in the ileum, mostly healed, but two large and recent ulcers; also some very small recent ulcers in the ascending colon.

SHEFFIELD PUBLIC HOSPITAL AND DISPENSARY.

FIVE CASES OF INTRAVENOUS INJECTION OF SALINE FLUID FOR HÆMORRHAGE AND COLLAPSE.[1]

(Under the care of Mr. R. J. PYE-SMITH.)

THE following cases, all of them of extreme gravity, have recently been treated at the Sheffield Public Hospital and Dispensary by a method which deserves to have more attention called to it. In THE LANCET of Sept. 12th, 1891, Mr. Arbuthnot Lane related a remarkable case in which he had saved the life of a child moribund from hæmorrhage by the intravenous injection of three pints and a half of saline fluid. Although the intravenous injection of watery fluid is as old as transfusion of blood, having been practised by Sir Christopher Wren in 1656, and being mentioned by Libavius in 1615,[2] it has not often been used in such large quantities as those employed by Mr. Lane, except in cases of cholera, in which disease it was very successfully employed in doses up to four pints by Dr. Little at the London Hospital in 1848–49, and again by Mr. L. S. Little in 1866–67. The quantity of fluid used is, however, one of the most essential points in the intravenous injection of saline fluid. However valuable and necessary the red corpuscles and the nutritive constituents of the blood may be, it is not their diminution that gives rise to the immediate danger in cases of acute hæmorrhage. The real cause of death is a mechanical one, and consists in the loss of volume in the circulating fluid, which must, within certain limits, be proportional to the capacity of the vascular system. These limits are practically defined by the action of the vaso-motor apparatus, which, within them, automatically regulates the tension throughout the arterial system; but as soon as the limit is over-reached in the way of depletion, the regulating power which adapts the tension of the vessels to their contents ceases, the toneless arteries then fail in their share in the propulsion of the blood, and—the capillaries, the veins, and the heart being each affected in its own way—the circulation flags, and ultimately ceases. This fatal condition is reached when the quantity of blood is suddenly reduced to between three-quarters and half the normal or actually present amount in the body, and therefore long before death would have resulted from the diminished quantity of red corpuscles or from loss of nutritive material in the blood. It is not the composition of the blood but its bulk that is at fault, and the result is not oxygen starvation or tissue starvation, but failure of circulation. The rational way to meet this emergency is the intra-vascular injection of a sufficient quantity of any fluid not injurious to the blood or to any of the tissues of the body. Such a fluid we have ready to hand in "normal saline solution"—i.e., ¾ per cent. aqueous solution of sodium chloride. The fluid is prepared by dissolving clean common table salt in clear, recently boiled water in the proportion of a drachm to the pint. It is injected into any convenient vein, at the rate of a pint in ten minutes, at blood heat, and in quantities sufficient to restore fulness to the pulse or to equal the amount of blood lost; and as in cases of death from sudden hæmorrhage the amount lost is usually from three to four pints, that should probably be about the quantity employed. The apparatus Mr. Pye-Smith has employed for injecting has been, except in the first case, a simple glass syringe, as recommended by Mr. Lane, to the nozzle of which a T-shaped piece of tubing has been attached, the other arms of which were connected respectively, by means of india-rubber tubing, with the cannula in the vein and the saline solution in a jug. With the help of an assistant to compress the two indiarubber tubes alternately it is quite easy to inject continuously with such an apparatus without danger of injecting air into the vein.

CASE 1. *Gunshot wound of leg; hæmorrhage; collapse; injection of three pints of saline fluid; amputation of leg; recovery.*—H. W——, a carter aged twenty-six, was admitted on Sept. 25th, 1891. He was accidentally shot in the left leg by the discharge of a fowling-piece at a distance of two or three yards, and sustained a severe lacerated wound, with compound comminuted fracture of tibia and fibula. He bled profusely for half an hour before being got to a house, where a handkerchief bandage was tightly applied to the thigh by a priest, and he was sent in a cart to the hospital, a distance of twelve miles. He arrived about three hours after the accident, and was admitted under the care of Dr. Keeling, in whose absence and that of Mr. Thorpe Mr. Pye-Smith was called to see the patient.[3] He found him much blanched and collapsed, with small, weak, and frequent pulse and cold extremities. The man was restless, and complained of pain and thirst. It was evident that the leg required amputation, but the patient seemed quite unfit to undergo such an operation, and Mr. Pye-Smith determined to try the injection of saline fluid before submitting him to it. Meanwhile, hot water bottles were applied to the body, and he was ordered a drachm of brandy with five minims of laudanum every half hour in an ounce of hot water. Ether

[2] South's Chelius.

[3] Mr. Pye-Smith thanks Dr. Keeling, who was away on his holiday at the time, for leave to report the case, and Mr. Thorpe, who arrived at the hospital half an hour after him, for having kindly left the case in his hands.

Digitized by Google

having been administered, and the thigh freed from bandages, Mr. Pye-Smith cut down on the internal saphenous vein below the knee at the level of the line for the proposed amputation flap. No blood flowed from either end of the divided vein, and it was not tied. A pint and a half of saline solution was slowly injected, with obvious improvement in the pulse, which had before become so feeble as to be scarcely perceptible at times. An elastic bandage was now applied to the thigh, and the amputation, two inches below the knee, was proceeded with; but when completed, although there had been scarcely any further loss of blood, the patient's condition was so alarming that the vein was again exposed by slitting up the skin over it, as the flaps had already been stitched together and the injection repeated. Another pint and a half of saline fluid was injected, this time with still more obvious effect, for the pulse became most markedly fuller and less rapid, whilst the colour and fulness of the face were distinctly increased. The patient soon rallied, took liquid nourishment readily, and in a few hours seemed out of immediate danger. The wound healed well, and was quite closed in a month. The man is now in good health, and by no means anæmic.

CASE 2. *Fractured ribs and internal hæmorrhage from a fall of thirty feet; collapse; injection of twelve ounces of saline fluid; death; necropsy.*—H. H——, a joiner aged thirty-two, was admitted on Dec. 15th, 1891. Whilst at work on the scaffolding of a new building he was struck by the chain of a crane, and fell a distance of thirty feet on to his left side. He was at once conveyed to the hospital, where he was seen by the house-surgeon, Dr. G. Wilkinson, half an hour after the accident. He was then in a state of extreme collapse, blanched and cold, but conscious, and complaining of pain in the left side. The pulse was very feeble, 120. The pupils were dilated and insensitive to ordinary daylight. The skin was covered with cold sweat. There was much pain in the back on movement. Crepitus was felt over several of the lower ribs on the left side, and there was a hæmatoma on the left buttock. On drawing off the urine, it was found to contain a trace of blood. The patient stated that he had micturated shortly before the accident. He was put to bed with hot-water bottles, and brandy and opium were administered, and ergotine was injected subcutaneously; but in the course of an hour he was evidently worse and almost pulseless. He was quite unfit for abdominal exploration, and, as a forlorn hope, saline fluid was injected into the cephalic vein at the right elbow. By the time that twelve ounces had been slowly injected the breathing had become so feeble that artificial respiration was resorted to, with the effect of somewhat restoring the pulse for a short time. Ether was injected subcutaneously and brandy was added to the saline fluid for further intravenous injection, but respiration and circulation failed before any more could be used, and in spite of continued artificial respiration, with inversion of the body and faradization, he died three hours and a half after the accident. At the post-mortem examination it was found that the lowermost five ribs on the left side were fractured and that there was a rent in the centre of the left half of the diaphragm through which the spleen and the greater part of the stomach had escaped into the left pleura. The spleen was quite pulped, and there were upwards of two pints of blood in the left pleural cavity, besides a considerable quantity in the posterior walls of the abdomen. The stomach was a good deal bruised, and the left kidney somewhat so. The bladder was not injured. The heart was contracted, and its ventricles were empty.

CASE 3. *Burnt wound of popliteal space; hæmorrhage; collapse; injection of sixteen ounces of saline fluid; amputation of thigh; recovery.*—J. O——, a steel roller aged eighteen, was admitted on Dec. 15th, 1891. He was at work in a steel-rolling mill when a piece of hot steel ran against him, cutting and burning the back of the left thigh down to the bone at the top of the popliteal space. He bled a good deal at the time, and, although a string was tied tightly round the thigh, he lost some more blood whilst being conveyed to the hospital. On admission an elastic tourniquet was applied, and it was found that the popliteal vessels and nerves were severed, as well as the biceps and parts of other muscles. Over a pint of blood-clot was found in the trousers. He was blanched and restless, and his extremities were cold. The pulse was small and feeble, 84. He was put to bed with hot-water bottles; an enema containing brandy was administered, and brandy and opium were given by the mouth. He would not at first consent to amputation, but within an hour of admission, his pain being so great, his friends prevailed upon him to do so, and ether was then at once administered. His condition was such that Mr. Pye-Smith thought it best to inject some saline fluid before amputating. Sixteen ounces were accordingly injected into the right cephalic vein at the elbow, with the effect of raising the frequency of the pulse to 120, and with such marked improvement in its volume that he then desisted, and proceeded to amputate the thigh by a single antero-internal flap, by which means he was able to divide the bone within an inch of the level of the wound and just above the apex of the popliteal space. The patient was pale for some days after the operation, but under the influence of iron and nourishment he soon began to regain his colour, and has made a very good recovery.

CASE 4. *Railway crush of both legs; hæmorrhage; collapse; double amputation (knee and thigh); injection of four pints of saline fluid; recovery.*—C. R——, a shunter aged thirty-nine, was admitted on Jan. 2nd, 1892. He was engaged coupling two empty railway trucks as they were slowly moving, when he slipped, and one of them went over both his legs just below the knees. Elastic tourniquets were quickly applied by some of the Midland Railway officials, but not till he had lost a good deal of blood, and he was sent to the hospital. When admitted he was much collapsed and moaning with pain, but it was not possible to get from him any account of the accident or even to obtain any response when he was told that his legs must be amputated. The right leg was found to be severed, except for a little skin, in the lower fourth, and was crushed to within two inches of the knee-joint. The left leg was nearly severed immediately below the knee, and the skin all round the knee was loose. His wife's consent to amputation having been obtained, ether was administered, and both legs were amputated, the right by lateral flaps through the knee-joint, leaving the semilunar cartilages as well as the patella; the left, by anterior and posterior flaps, just above the condyles, the patella being removed. Very little blood was lost, but his arteries felt very empty. The pulse was irregular, soft, and compressible, 132. His face was very pale. It was not considered advisable to leave him without injecting saline fluid, which was in readiness; and, as he lay quiet after the effects of the anæsthetic, it was easy to inject the fluid into the internal saphenous vein at the angle of the amputation wound in the left thigh, before applying the dressings. Four pints were steadily injected in the course of about half an hour. The effect on his pulse was marked; it fell in frequency from 132 to 104, and became much fuller, but he might probably have received still more with advantage. The face became a little less pale, but the improvement in that respect was not great. The pulse rose again to 120 before he was removed to bed, but he rallied well, and, though weak and very anæmic for a fortnight, he is now making a good, though slow, recovery. Unfortunately, a great part of the skin flaps of the left amputation wound sloughed, and an inch or more of the femur will probably have soon to be removed. There was also some sloughing in the right limb, but the tissues are now closing satisfactorily, and promise to make a good stump.

CASE 5. *Burnt wound of axilla; hæmorrhage; ligature of axillary artery; gangrene; secondary hæmorrhage; amputation at shoulder; syncope; injection of four pints of saline fluid; death.*—M. T. L——, a collier aged twenty-four, was admitted on Dec. 31st, 1891. In running between a fellow workman and the fire he received an accidental blow from a pointed piece of hot steel, which penetrated the left axilla from the front. Blood spurted out of the wound, but pressure controlled the hæmorrhage till medical assistance was obtained. Mr. Pye-Smith saw the case at Waleswood Colliery in consultation with Mr. G. H. West Jones of Eckington five hours after the accident occurred. There was a small wound about two inches above the anterior axillary fold on the left side, and the axilla was distended, but the radial pulse on that side was as good as on the other (88 per minute), and sensation in the limb was perfect. With the assistance of Mr. West Jones and of Mr. J. Court of Staveley, Dr. A. Court giving chloroform, Mr. Pye-Smith opened up the axilla from below, and found it full of blood-clot. The burnt wound went directly backwards, through the pectoralis major, and penetrated to the vertebral border of the scapula. A large artery (probably the subscapular) was found bleeding, and was secured deep in the axilla, as well

Digitized by Google

as one or two smaller vessels, and it was hoped they would prove to be all, as the axillary vessels and nerves appeared to be uninjured; but on moving the arm blood rushed from the axillary artery, and it was found that there was a slit on its upper aspect in the third part of its course. It was tied and the wound then closed, drainage-tubes being inserted, and, as the man's home was two miles from the colliery, he was then sent in an ambulance to the hospital, a distance of about ten miles. Next day there was lack of sensation in the fingers, and on the following day, as gangrene appeared to be commencing, a consultation was held to decide whether to amputate at once at the shoulder or to wait for demarcation. It was decided to wait, in the hope of being able to amputate at the elbow later on, sensation still being good to some inches below that joint. In the course of a week the gangrene had greatly advanced to just below the elbow, and now a gangrenous patch showed itself on the inner aspect of the upper arm. The patient became delirious and the semi-purulent discharge from the wound was fetid. He took nourishment pretty well, but the pulse and temperature ranged high, and he looked very pale, thin, and ill. On the evening of Jan. 12th (twelve days after the accident) secondary hæmorrhage occurred, and he lost several ounces of blood. It was evident that amputation must be at once performed and the bleeding vessel secured. Ether was accordingly administered, and it was found that the gangrene now extended to the middle of the arm. Amputation at the shoulder was effected by outer and inner flaps. No large vessels bled, the axillary artery being plugged with clot and the slit in it being clearly visible. On clearing out the suppurating cavity in the axilla, it was seen that the secondary hæmorrhage was from a hole deep down on the vertebral border of the scapula, so deep that the only way to secure the vessel was by leaving a pair of long pressure forceps on it. It was apparently the posterior scapular artery, which had ulcerated on the separation of an eschar caused by the burn. Whilst this vessel was being secured the patient's pulse entirely failed, and two pints of saline fluid were at once injected into his right basilic vein, with marked improvement in his aspect, and a return of the radial pulse, which became full and bounding. In a few minutes, however, the pulse again began to disappear, and was soon imperceptible at the wrist. Ether was injected under the skin and a brandy enema given, and then the saline injection was resumed. When half a pint had been used the pulse again returned, and continued to improve whilst the remainder of the second quantity of two pints was being injected; but it never became as strong as it did during the previous injection. When the injecting was finished the respiration was very feeble and shallow, and the pulse soon became imperceptible even at the groin, and breathing ceased. Artificial respiration was now resorted to, combined with inversion of the body, and faradaism was applied to the neck and præcordium, but none of these means availed to restore either circulation or respiration, though persisted in for half an hour.

Medical Societies.

ROYAL MEDICAL & CHIRURGICAL SOCIETY.

Ligature of the Second Part of the Left Subclavian Artery for the Cure of Axillary Aneurysm.—Symptoms and Pathology of Psilosis.

AN ordinary meeting of this Society was held on April 12th, Sir Andrew Clark, Bart., President, in the chair.

Mr. GODLEE read a paper on a case of Ligature of the Left Subclavian Artery for the cure of an Axillary Aneurysm. The subject of this paper was a man aged sixty-six, who was suffering from a large axillary aneurysm on the left side, with dilatation of the left subclavian artery and signs of pressure on the brachial plexus. There was also some suspicion of atheromatous disease of the aorta. Tuffnell's treatment was employed for three weeks without effect, and the aneurysm appeared to be increasing in size. The subclavian artery was accordingly tied in its second part with catgut. The wound healed by first intention and the aneurysm was gradually contracting. The patient complained of pain in the upper arm. Appended were notes by Dr. J. Mitchell Bruce, describing the condition of the thorax both before and after the operation. The justifiability of the operation, the best method of performing it, and the best form of ligature, were finally discussed.—Mr. BARWELL agreed that the old statistics on this subject were valueless, as, owing to the advance of surgery, those complications formerly so common were now no longer to be feared. In 1879 he had operated by a somewhat similar method, and in his writings he had more than once recommended it. He referred to a tabulated list of nine operations of this kind, and mentioned the causes of death in the five which succumbed. The artery being well supported by muscle fibres between the scaleni was less likely to be diseased there, and hence would better bear a ligature. This aneurysm was much rarer on the left side, and it appeared from Dr. Bruce's description of the present condition of the chest that other large arteries were involved, probably by a prolongation of the aneurysmal condition downwards. This complication was always to be feared in these cases.—Dr. TAYLOR said that the patient, who had resumed his occupation, stated that he was weaker than he originally was, though he now only complained of a slight pain over the heart. After the operation there was considerable pain of a neuralgic nature in the left arm.—Mr. MAUNSELL said that suppuration in the sac and secondary hæmorrhage were causes of death in these cases. The former had been practically abolished by antiseptic surgery, and, with regard to the latter, time alone could show whether it would be possible to ligature successfully the second part of the subclavian on the right side; that vessel being almost in a straight line with the ascending aortic arch, and therefore exposed to the full force of cardiac contraction; it also had branches springing from it, which was not the case on the left side.—Mr. HOLMES congratulated the author on the success of the operation, and remarked on the necessity of keeping an accurate record of all the cases He himself had never resorted to this procedure nor had he seen it done, but he remembered an instance in his own experience in which he would have been better advised had he endeavoured to tie the second part instead of the third; the aneurysmal sac was so much in his way that in endeavouring to apply the ligature he perforated it and the man bled to death. There were of course dangers in the operation, but personally he did not regard the possibility of injuring the thoracic duct as a very serious one, for it was a lax structure and not liable to be wounded; on the other side ligature of the superior intercostal nerve had to be guarded against. The use of ligatures which no longer cut through the coats of the vessels had greatly diminished the risk of secondary hæmorrhage. Statistics drawn from the past were valueless, for the practice of Liston and Astley Cooper was something quite different to that of the present day, and their experience was practically useless. As to the material used for ligature, he himself had used ox aorta with much success, though he admitted that the catgut ligature was, if not superior, at any rate equal to any other. For general use, however, he preferred kangaroo tendon; it was less bulky, more easily tied, and more trustworthy than catgut. As the latter was prepared by a process of putrefaction, it could not so easily be rendered perfectly aseptic, and this was a point of great importance in relation to the so-called secondary, but in reality primary, hæmorrhage, which had proved so fatal. He preferred so to ligature the vessel as to divide the internal coats. These cases were exceedingly dangerous, and their fatality was due to the fact of the proximity of the vessel to the aorta.—The PRESIDENT agreed with Mr. Holmes when speaking of the uses of past statistics; they were not only unreliable, but misleading.—Mr. GODLEE, in reply, said that in the paper to which he had referred there was an account of eight cases, and in five of them the ligature had been applied between the scaleni. The phrenic nerve was usually quite out of the way of injury, but the duct stood in greater danger of being divided. It was situated in a region in which surgeons had carried out extensive operations for the removal of glands, and he had seen the duct or a large tributary thereof divided in a woman, who subsequently became very much emaciated. He felt sure that silk would answer perfectly well to ligature the artery in its continuity; still a ligature made of several strands of catgut could be easily placed and tied into a very small knot.

Dr. GEORGE THIN gave a communication on the Sym-

Digitized by Google

ptoms and Pathology of Psilosis Linguæ et Intestini. The author referred to his previous publications on the symptoms and pathology of this climatic affection, and illustrated the characteristic changes in the mucous membrane of the mouth and throat by relating in detail the histories of two typical cases, the appearances being illustrated by water-colour drawings. In order to emphasise the points of distinction between psilosis and other forms of tropical diarrhœa, he related the histories of two cases of the latter affection; and showed on what symptoms the differential diagnosis depended. In the two cases of psilosis which were now specially described, microscopic examination by Dr. Wethered of large, creamy, soft masses, which were passed with the stools after the motions had become solid, showed that they consisted of almost pure cultivations of bacteria, a rod-shaped bacterium, of moderate and definite size, largely predominating over the other organisms present. With convalescence, this mass gradually diminished in quantity, and, when recovery had taken place, was no longer observed. The mass was much larger in one of the cases than in the other, but the characteristics were the same in both. In the liquid diarrhœa motions of the acute condition the colour of the stools was a pale yellow; but when the diarrhœa had ceased, and the motions became solid, the patient passed, usually once daily, a large, formed, white, colourless stool; the colourless condition of the motion coinciding—over weeks and months—with a diet containing milk, farinaceous foods, fish, eggs, and chicken, with a moderate amount of vegetables and fruit. Six cases were referred to in illustration of this fact. Clinical evidence, and the evidence of a previously published case—in which there was a post-mortem examination—was adduced to show that these white stools were coincident with a normally healthy condition of the liver and pancreas. In one of the cases the fæces, on a pure milk diet, were analysed by Dr. Wynter Blyth, who associated himself with the investigation of this part of the case; and it was shown that the general percentage composition was: water, 82·73; organic solids, 14·00; chemical matters, 3·27. More than half of the organic solids consisted of neutral fats, apparently milk fat, which had passed without being digested or saponified. Nearly 6 per cent. of bile acids were present as a soap. A small quantity of organic sulphur was present as taurin, but the colouring usually found in fæces was entirely absent. As the fat in the stool was only a fraction of the quantity taken in the milk, it followed that a considerable proportion of the milk fat was digested. In both cases the exhibition of iron was not followed by the ordinary black iron stool, minute grains of metal being interspersed with the motion. Reference was made to a paper by Allan Macfadyan, Nencki, and Nieber, in which, in a case of fistula near the ileo-cæcal valve, it was shown that the food mass which passed into the colon was acid, whilst the reaction of the mucosa of the ileum was alkaline; and both the mucosa and the contents of the large bowel were alkaline. Reasons were given to show that in psilosis the alkaline secretion of the mucosa of the ileum was wanting; that the food mass that passed into the large bowel was more than usually acid; and that the fæces were acid. It was argued that the abnormal reactions of the intestine must produce abnormalities in the development of the bacteria normally present in the bowel; and it was suggested that the normal colouring matter of the stools, under the influence of abnormal bacterial products, either was not formed or was destroyed. The same condition, but to a less marked extent, obtained in some cases of ordinary tropical diarrhœa. Clinically, the fact was established that persistent white stools might exist, whilst both the liver and the pancreas were healthy.—Dr. ECCLES said that he was in a position to confirm what had been said by the author as to the condition of the intestinal contents in this very rare disease, and he referred to a paper read by him at the International Congress at Berlin in which he demonstrated that the action of salol was greatly prolonged in certain forms. He had found that when the motions were frothy and white, salol did not appear in the urine for three or even four hours after ingestion. That was a very marked prolongation, for in the healthy man it could be detected at the expiration of forty-five minutes. The explanation of this was presumably that salol was insoluble in acids, but easily so in alkalies, and it followed from this that if the salol were a long time before being split up, it must be in the presence of an acid medium. In certain cases of sprue under his notice it was found that when the motion was yellow or white and frothy, and for some time after the motions had become cylindrical, but still white, the delay in the appearance of salol was still prolonged, but when the motions became coloured as well as cylindrical, the reaction of salol appeared much more promptly, taking place in as short a time as fifty minutes. Persons might have a slight attack of sprue in a country where the disease was met with, and then the disease would seem to cease and the patient return to this country. But as long as ten years afterwards a period of cold, damp weather would determine a fresh outbreak. He had had an opportunity of applying Gunnsberg's test as to the condition of the digestive juices in sprue, and had found that there was but little gastric activity; there seemed to be an over-secretion of hydrochloric acid, from which it followed that gastric digestion might be prolonged after the food reached the small intestine, and so set up the condition of irritable ileum referred to by the author.—Dr. SCRIVEN said that sprue was quite a different disease from ordinary tropical diarrhœa; it was common in the Himalayan highlands, and had been attributed to the water. It was very chronic, extending over several years, the patient getting gradually thinner, with enfeebled digestion, associated with vomiting and sore mouth. The abdominal organs were usually found wasted, but apparently healthy; he had occasionally seen ulceration of the large intestines, but in that case he considered that the disease had been superadded to dysentery. He had also met with a kind of roughness of the ileum which seemed to form part of the disease, though as a rule the mucous membrane was smooth and thin. The most important observation of recent years with regard to the disease was that it could be cured by the aid of milk, and without medicine. He was in the habit of ordering three ounces an hour for sixteen hours daily, gradually increasing the quantity to six pints per diem. Where there was much trouble in inducing the patients to keep to the milk diet he allowed a small quantity of bread to be crumbled with the milk, and he referred to an instance in which wonderful improvement took place after seven weeks, even although a small quantity of bread had been allowed. In another case, where the patient had suffered from diarrhœa for three years, when on a milk diet the trouble ceased, and the motions became solid and white; when that occurred, the patient at once, against advice, took to general diet, with the result that a relapse took place; he repeated this five times in one year, and eventually died of the disease.—Dr. MANSON referred to the work of Bertrand and Fontan on the "Enterocolite chronique des Pays Chauds," in which they gave an account of the pathology of the disease. He himself did not regard the disease as an endocolitis, but thought that it was a condition generally superadded to some previously existing affection, such as dysentery, operations upon the lower part of the bowel, such as piles, fistula, &c., and in debilitating conditions, such as pregnancy, hæmorrhage, fatigue, mental worry, and depression. There occurred in the tropics forms of the disease in which the lower bowel was not involved, the typical tongue being present, together with dyspepsia and white stools; this condition might remain without advance for months if the patient were careful as to diet, but any error in this direction might initiate a well-marked attack, extending down the alimentary canal. It was of the utmost importance in treatment to procure physiological rest to the digestive apparatus, the patient being sent to bed so that the nourishment of the body might be carried on with the lowest possible diet capable of sustaining life. He began by ordering sixty ounces of milk, with directions that unless the diarrhœa ceased it was to be reduced ten ounces daily to a minimum of ten ounces. Patients who were refractory to milk diet could be given koumiss, which was just as efficacious. In one analysis the stools were described as containing a trace of bile acids, while in others these were altogether wanting. In several necropsies they found that the pancreas contained centres of degeneration and even suppuration; it was the most fatal of the chronic morbid conditions to which the Anglo-Indian was liable. French authors stated that in Cochin China the disease was just as common on the coast as in the interior and in low-lying districts as on the highlands. The mortality among the army of occupation had been enormous from this cause, and 10 per cent. of their deaths were ascribed to it.—Dr. JOHNSON said that the disease was at any rate indirectly caused by residence in malarial districts.

Digitized by Google

Though it had been met with as an idiopathic condition, yet a great many cases were consecutive to dysentery and malarial fever. Immediate change of climate gave the only chance of recovery, and it usually answered admirably if adopted in an early stage of the disease. From the fact that it was so very common in such places as the valley of the Yang-tse, Batavia, and other well-known hotbeds of malaria, it was impossible to avoid the conclusion that it was not merely a disease which might occur in any tropical climate, but that there must be some preceding malarial poisoning.—Dr. THIN, in reply, said that he had purposely avoided all allusion to treatment, with which he had fully dealt elsewhere. His particular object was to demonstrate the condition of tongue and throat peculiar to the affection. With relation to the existence of white stools, they had been taught by tradition that a temporary condition of this kind indicated inaction of the liver amenable to appropriate medication; but this was an affection not associated with the liver, and yet accompanied by colourless motions. He did not admit that it was a malarial affection, for though it occurred in countries where malaria was common, yet plenty of people suffered from malaria without having this disease, and it also existed in countries where malaria was unknown. He had been struck by the number of French troops which had been affected, but they probably included all cases of tropical diarrhœa under this head. Though it was apt to attack people weakened by age or pre-existing maladies, it also attacked the young and the strong. He quoted a case in which the malady could not have been superadded to any pre-existing disease, and he maintained that if the disease attacked weak people, the weakness had nothing to do with it. He quoted several opinions to show that the disease was not the same as the "hill diarrhœa" of India, and referred to the difficulty of distinguishing between it and the "sore mouth" of Ceylon. With regard to the condition of the pancreas, he observed that that organ was found to be healthy in the majority of cases examined.—The PRESIDENT desired to call attention to the similarity between this affection and certain varieties of disease known in the provinces as "mucous disease."

MIDLAND MEDICAL SOCIETY.

WEDNESDAY, MARCH 9TH.

Mr. BENNETT MAY, F.R.C.S., President, in the chair.

Piece of Brass in Lens.—Mr. ANTROBUS showed for Mr. Eales a lad aged fourteen, brassworker, with a piece of brass situated in the lower and outer part of the crystalline lens, which had been there fourteen days, the lens retaining its transparency.

Perforated Appendicitis.—Mr. RATCLIFFE showed a case of perforative appendicitis. H. W——, aged fifteen, glass-worker. Five years ago the patient was in hospital suffering from typhoid fever. On Jan. 22nd he returned from work seeming well. He lay down on the sofa, and soon afterwards complained that he had the "bellyache," the pain being in the upper part of the abdomen, above and in the region of the umbilicus. He came to the hospital and was treated as an out-patient. On the following day (23rd) he was admitted as an in-patient, under the care of Dr. Wilson. There was no constipation before the commencement of the illness, but it was marked after. On admission, the abdomen was distended all over. No tumour could be felt anywhere, and the pain was almost entirely confined to the left iliac region, there being little or none on the right. The patient continued in this condition till the 30th, when he suddenly became collapsed, with profuse perspiration and feeble pulse, and the abdomen became extremely distended and tender. He was taken to the theatre for operation, but died before it could be done. Necropsy: The small intestine was somewhat distended throughout. There was marked general purulent peritonitis. Over the anterior surface of the vermiform appendix a piece of small intestine was matted by peritonitis so as to form an abscess cavity the size of a walnut, the upper boundary being the last two inches of the ileum, the outer wall formed by the cæcum. This cavity had burst into the general peritoneal cavity. The appendix was hidden in this cavity. There was a stump a quarter of an inch long attached to the cæcum. This stump had its lumen occluded. The rest of the appendix was adherent to the wall of the abdomen outside the cavity. No calculus could be found. There was no pus behind the cæcum. In the left iliac fossa there was a coil of small intestine more markedly inflamed than the rest, but nothing else.—*Remarks:* It is interesting to note that this boy had had typhoid fever previously, this probably causing narrowing of the opening of the appendix, which, becoming blocked, had formed a cyst, not giving rise to any symptoms. The first symptoms would be probably due to rupture of this cyst. Adhesions forming the second and final symptom were due to the bursting of this into the general peritoneal cavity. Perhaps the most interesting feature of the case is that at no time could any particular tenderness or any signs of tumour be discovered in the right iliac fossa. In the first instance the pain was above the umbilicus, and after admission entirely confined to the left iliac fossa, rendering the diagnosis of appendicitis wellnigh impossible.

Cysticercus Cellulosæ.—Mr. RATCLIFFE also showed a Cysticercus Cellulosæ in the Arm. J L——, a middle-aged man, who lived largely on pork and bacon, came up complaining of a small swelling, about the size of a large hazel nut, on the inner side of the biceps muscle of the right arm. It had been growing for a year, and had given rise to pain for the last two months. On removal, it was found to be a small cysticercus about half an inch in diameter.

Imperforate Anus with a Penile Fistula.—Mr. Heaton showed an infant on whom he had operated for the relief of imperforate anus with a penile fistula. The child, an otherwise healthy male infant, had on the under surface of its penis, about three-quarters of an inch from the end of the glans, a small fistula, from which for the first few days of its life a constant discharge of meconium took place. The anus appeared natural, but on examination was found to lead into a blind cul-de-sac. The rectum was found about three-quarters of an inch from the end of the anal cul-de-sac. It was opened and its mucous membrane stitched to the edges of the skin incision. The opening of the fistula into the rectum was on its anterior surface about half an inch from the blind end. The fistula had no connexion with the urinary passages. Since operation the child had gained in weight, and at present there was no tendency to contraction of the newly made anus.

Mr. HEATON read a paper on Anæsthetics.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.

TUESDAY, FEB. 6TH.

ROBT. MERCER, M.R.C.S., President, in the chair.

MR. ALTHORP showed a patient recovering from Compound Comminuted Fracture of the Patella.

Auto-infection in Scarlatina.—Dr. BATES read notes of a case of apparently typical Scarlatina in a girl of nineteen, who, having complained of slight joint pains at the end of the first week, was apparently in the course of convalescence when the temperature ran up and the typical rash again appeared. On the fourteenth day the urine was albuminous, with blood and casts present; on the seventeenth some erythema nodosum appeared; on the twenty-first day the rash came out again, and after this the fever abated. On the thirty-fifth day the urine became scanty, and œdema of the face appeared. Hot-air baths re-established diuresis; desquamation continued until about the eightieth day. He was at a loss to account for the symptoms except on the hypothesis of auto-infection.—Drs. Carter, Burnie, Rabaghati, and Johnstone criticised the case.

Antipyrin in Asthma.—Dr. BATES read notes of two cases in females. In one abortion had occurred from the severity of the attacks. Local measures and arsenic, pushed to the extent of a drachm of the liquor in the day, had been useless. A large dose (twenty-five grains) of antipyrin gave the first relief for months. Both cases had relief now under continued treatment with antipyrin.

Hæmatocele.—Dr. GOYDER read a paper dealing with the Pathology and Treatment of Pelvic Hæmatocele, especially the later stages. He dwelt on the obscurity of the diagnosis occasionally, and advised medical rather than surgical treatment for the majority of cases.—Mr. HORROCKS strongly advocated surgical treatment; the medical treatment he regarded as trifling.—Dr. JOHNSTONE mentioned three cases treated expectantly, in each of which an ovum

Digitized by Google

was found post mortem.—Messrs. Carter and Burnie also spoke.

Tumour of Optic Thalamus.—Dr. MAJOR showed preparations and specimen, and read the notes of the case of a single girl aged twenty-three. Four months prior to admission she had pains in the left temporal region, worse at night. She could read perfectly, but noticed that on looking at two people she only saw the left one. Two months later she sought treatment for her sight; one eye was hemiopic. Five weeks later she suddenly lost power in right arm, leg, and side of the face. There was some numbness of the right side and thickness of speech, but no aphasia or loss of consciousness. She regained power to a great extent, and three weeks later had a similar attack, from which she was recovering on admission, when she was bright and intelligent. Temperature a little raised. Right pupil dilated; no optic neuritis, no colour-blindness. Right synonymous hemiopia, paralysed muscles, flaccid. Diagnosis, tumour of posterior part of left optic thalamus pressing on posterior limb of inner capsule. Iodides were given. The fever increased, delirium commenced, then prolonged stupor and death. Post mortem, some meningitis, left optic thalamus distinctly enlarged, and on section the posterior part contained a rounded, firm, slightly greenish-coloured tumour, which pressed on the posterior portion of the inner capsule The structure was not typical, microscopic examination showing nests of large ill-defined cells embedded in a fibrous tissue.

PLYMOUTH MEDICAL SOCIETY.

SATURDAY, MARCH 12TH.

Mr. T. LEAH, President, in the chair.

MR. WALTER WOOLLCOMBE showed a case of Double Congenital Dislocation of First Phalanges of Thumbs forwards into Thenar Eminence. The phalanges, especially of the right hand, were very poorly developed, and the thenar eminences entirely wasted. The patient, a man aged forty-one, was a tailor, able to work well till lately, when he had suffered from "sewing cramp" in the first and second fingers. He presented a curious deformity of back—the upper sacral and second lower lumbar vertebræ presenting extreme bulging posteriorly—prominence covered by tuft of long hairs—spina bifida occulta (Sutton), and a compensatory curve forwards of the lower dorsal vertebræ very extreme, so that a deep fissure existed between the erector spinæ muscles.

Mr. A. RENDLE showed a Gall-stone of unusual size passed per anum by a stout woman, aged forty-nine. Severe colic for three months, with slight jaundice; melæna; hæmatemesis on two occasions. A large inflammatory mass could be felt in the neighbourhood of the gall-bladder. Exact size of stone, 1·8 in. in length, 1·2 in. in breadth; weight just over three drachms. Mr. Rendle remarked that he could only find records of two doubtful cases exceeding this in size, and two others where hæmatemesis was noted as a symptom.

Mr. WM. SQUARE opened a discussion on the Relative Values of Temperatures. After describing the thermometer as first introduced, and the improvement in late years, he emphasised the fact that external circumstances have little or no effect on the internal body temperature, and cited some common causes of a raised temperature where no lesion could be found. The amount of temperature was equal to the amount of tissue metabolism in excess of normal. He next raised the question of the value of drugs simply to bring down the temperature in such diseases as typhoid fever; in his opinion they were of no use. He cited 110° as the highest temperature consistent with life, and concluded by discussing the hyperinosis theory.

Mr. H. S. THOMAS showed the following charts:—1. Acute Rheumatism, in which each rise above the average coincided with fresh joint pains, and *vice versâ*. 2. Third Week of Typhoid, in which fall of temperature was interrupted by occasional rises, each accompanied by either diarrhœa or fresh spots. 3. Acute Pneumonia, temperature falling on seventh day; rise after reaching normal, coincident with serious symptoms, although no evidence of fresh consolidation could be found. 4. Acute Epididymitis, with heart murmurs, varying much in intensity, in which the temperature rose every evening between 2 and 10 o'clock to 102° or 103°. Quinine was useless; ulcerative endocarditis was diagnosed. 5. Tubercular Arthritis of Ankle. Temperature 103°; collection of pus let out; temperature fell for the week, then rose again. Amputation. Temperature kept up, although stump looked well; probably deep and extensive thrombosis. 6. A Case of Lupus, in which chloroform was given for scraping. Sudden collapse; artificial respiration &c.; on recovery temperature was 101°. One hour later it had dropped to 98°, and then remained normal.—Mr. WILLOUGHBY thought that in acute rheumatism, lobar pneumonia, and affections of the pons where the temperature reached 106° or 107°, the temperature alone should be treated by drugs, irrespective of the disease. The most effective treatment was cold baths, and the patient should be removed before the temperature had fallen as low as desired, as it continues to fall after removal.—Mr. A. RENDLE would go further than the last speaker, and sponge whenever the temperature reached 103°. No harm ever resulted.

Reviews and Notices of Books.

The Anatomical and Histological Dissection of the Human Ear in the Normal and Diseased Condition. By Dr. ADAM POLITZER. Translated from the German by GEORGE STONE. London: Baillière, Tindall, and Cox. 1892.

THIS work gives in detail various methods for the anatomical investigation, coarse and minute, of the various parts of the ear in health and disease. The book is very thorough, entering into all the minutiæ in the most complete manner. The first part, which comprises six chapters, deals with the naked-eye appearances of the various parts of the organ of hearing, the removal of these from the body, the making of sections through them, and the description of elaborate and complicated dissections to display their appearance in the normal state and otherwise. The second part deals in detail with the histological methods most in vogue among pathologists and anatomists who especially investigate the organ of hearing. This part of the work is most instructive, and contains all that is new and important in connexion with the examination of the complicated structures with which it deals. The translation is, on the whole, very readable, and Mr. Stone may be congratulated on having executed his difficult task well. The work is illustrated by 164 illustrations and one woodcut.

The laborious investigations of Toynbee in the pathology of the organ of hearing did much to place aural surgery upon a scientific footing. True advance in this subject can only be hoped for by increased knowledge of the physiology and pathology of the complicated inner ear. Anyone reading this book will at once see that it forms a most valuable guide to the would-be dissector and pathologist. The reader will also be somewhat dismayed at the great amount of labour, time, and close attention that must be bestowed without stint by him who would become an expert in, or advance, aural pathology. The work, indeed, is a powerful argument for the subdivision of labour in modern pathological investigations, and shows us that in this country we are somewhat behind our German *confrères* in the minute investigation, post mortem, of cases of deafness. What has been said of this book is sufficient evidence of its extreme value to any worker in aural pathology. Its study becomes a necessity, for it stands unrivalled. It should form part of every hospital library and be in the bookcase of all those who wish to investigate diseases of the ear by the light of post-mortem examination.

Traitement des Maladies de la Peau. Par le Dr. L. BROCQ. Paris: Octave Doin. 1892.

THE fact that a second edition has been called for in eighteen months shows that this valuable work of the new French school has met with the appreciation of those for-

Digitized by Google

whom it was intended. It only remains for the critic to point out in what way this edition differs from its predecessor. In the first place, *mirabile dictu*, the number of pages is reduced from 925 to 894, and that, indeed, although the author has added a chapter on those surface diseases of the tongue which most frequently come in the way of the dermatologist, such as leucoplakia, black tongue, the mapped tongue, or, as he calls it, "desquamation marginée aberrante," glossodynia, and superficial glossitis. While there is some reason for this notice of surface tongue affections, it is rather surprising to find several forms of vulvitis described in a work on diseases of the skin. The articles on eczema and lichen have also been extended, and there are new articles on actinomycosis, glanders and farcy, *maladie pyocyanique*, or skin lesions consequent on the presence of the bacillus pyocyaneus, parakeratosis, syringomyelia, &c. Although these new articles are short, yet they are additions; and how, then, has the reduction in size been effected By an improved eclecticism as regards the remedial measures suggested, the first edition having been overloaded with formulæ, to the embarrassment rather than to the assistance of the practitioner. The result is an undoubted improvement in the work; but we are not sure that it might not have been carried a little further still. Dr. Brocq has very wisely, too, had all his formulæ made up by an experienced pharmacist, so that those who consult his work may rely on the formulæ being composed on sound pharmaceutical principles. The work can therefore be advantageously consulted for French methods of treatment by all practitioners who are familiar with the language, and the alphabetical arrangement will facilitate their search. Some of the formulæ, such as that for the useful emplastrum Vigo, with its twelve ingredients, will astonish English readers; but they are only relics of ancient pharmacy, which experience has proved to be useful, and with regard to which no one in this age of bustle has taken the trouble to separate the wheat from the tares.

A Report of an Investigation into the Causes of the Diseases known in Assam as Kala-Azár and Beri Beri. By GEO. M. GILES, M.B., F.R.C.S., San. Sci. Certif. Univ. London; Surgeon I.M.S., on special duty in Assam. Shillong: Printed at the Assam Secretariat Press. 1890.

Tea Garden Sanitation. Being a Few Remarks on the Construction of Coolie Lines and the Sanitary Management of Coolies, with Special Reference to the Prevention of the Disease known as Anæmia of Coolies, Beri-beri, and Anchylostomiasis. By GEO. M. GILES Surgeon I.M.S. Shillong: Assam Secretariat Press. 1891.

THE first of these publications is a scientific report of a very carefully conducted and interesting investigation by Dr. George M. Giles, and the second gives the practical results of that investigation in a popular form for the use of non-professional persons and the managers of tea gardens in Assam. The report, illustrated with several plates, begins with a comparison between the disease observed in Assam and that known as the beri beri of the Dutch colonies of Sumatra and Java, and long ago observed in Madras and described by Malcolmson. Dr. Giles satisfactorily demonstrates that the so called beri-beri of Assam is a totally distinct disease, however, marked by dyspepsia, anæmia, subnormal temperature, dropsy, and debility, and without any necessary connexion with any specific peripheral neuritis or disorder of the nervous system. It corresponds with the endemic parasitic anæmia observed at Ceylon, but not with the beri-beri of nervous origin. The beri-beri, or Kala-Azár, of Assam is due to the Dochmius duodenalis inducing a diseased condition, for which Dr. Giles proposes the term "anchylostomiasis." He shows by his researches into the life-history of the parasite that it is not in water, but in human excreta exposed to the air, that the ova of the entozoic worm find their nourishment and pass through the several stages which fit them again for a parasitic existence. The number of ova found in the dejecta of the subjects of anchylostomiasis is immense. The subsequent changes, the production of swarms of minute nematoid embryos, and the transmission of the disease in connexion with the habits of the natives, are all very carefully traced out and set forth. The author's labours are likely to be attended with great practical benefits, for, as he points out, there should be no difficulty in removing the source of the disease by a proper system of conservancy and sanitation, and he discusses very fully and practically the preventive measures necessary to that end. The mortality from this disease in the tea gardens and villages is very great, and every effort should be made to carry out the practical remedies indicated by the author of these excellent reports.

Dissection Guides By THOMAS COOKE, F.R.C.S. Eng., B.A., B Sc., M.D. Paris. London: Longmans, Green, and Co.

THE author is well known for his systematic arrangement of the facts of human anatomy and for the methodical manner in which he has successfully imparted instruction in a long series of years. "Dissection Guides" forms a useful volume, containing the result of much careful practice and knowledge. The object of the book is to make dissecting a fascinating pursuit. Under the guidance of proper instruction there is no subject of the whole medical curriculum which excites so much enthusiasm in the student. Mr. Cooke points out correctly the causes of that vexation and disappointment which in the case of the student of anatomy lead to destruction of "parts," render the attainment of knowledge imperfect and out of ratio to the time spent in its pursuit, and eventuate loss of zeal, and finally distaste for the study. With a good teacher this to the student would be impossible. It generally arises from wrong methods on the part of the instructor. The keynote of the book is struck in the following sentence:—"But for repeated dissections to be possible in the present congested state of the medical curriculum the student must learn to dissect both efficiently and without loss—i.e., unnecessary expenditure—of time; he must learn to dissect well and quickly." The author's endeavour is to teach the student to do this, and there is no doubt that by following the directions laid down in the volume this power will be attained. Specially valuable s such a work to students who have dissected the parts already, but who are working for the higher examinations and require to refresh their knowledge. We notice with pleasure the author's views on the subject of pictorial illustration in the teaching of this subject. Drawings on the blackboard and elsewhere, when properly executed, are undoubtedly an aid to the apprehension and recollection of an intricate subject. But there is no occasion, whilst using such helps, to give them the main prominence. The book aims at benefiting the industrious student, at teaching him to dissect efficiently, and to obtain a practical acquaintance with the structures of the human body, which will stand him in good stead in his career as a surgeon. It will be found to be practical from beginning to end.

OUR LIBRARY TABLE.

Transactions of the Ophthalmological Society of the United Kingdom. Vol. XI. Session 1890-91. With List of Officers, Members, &c. London: J. & A. Churchill. 1891.—The eleventh volume of the Transactions of the Ophthalmological Society contains some valuable contributions to ophthalmic science. Foremost among them is a most lucid

Digitized by Google

and complete description of the glands of the ciliary body, with excellent photo-micrographic figures by Mr. E. Treacher Collins. The demonstration of these glands was rendered possible by the ingenious device of bleaching sections by means of chlorine, and the result is a most valuable addition to our knowledge of the histology and pathology of that part of the eye. The discovery is so entirely in accordance with the rest of our knowledge and anticipations that it may fairly be regarded as the keystone which completes the subject. The same author describes and figures a very remarkable case of rupture of the posterior capsule of the lens and one of implantation cyst in a shrunken globe. Mr. George A. Berry has some rather abstruse papers on the connexion between accommodation and convergence, and on latent lateral deviation of the eyes. Some exceptional cases of hemianopsia in which the condition of the brain was investigated post mortem are supplied by Messrs. Swanzy, Werner, and Williams. The above, with some other cases of interest and variety, make up a very good volume, which contains in addition the President's address on the work and events of the previous year and the Bowman Lecture delivered by Mr. Hulke. The coloured plates and figures are quite up to, if not beyond, their usual excellence.

Contributions to Practical Medicine. By Sir JAMES SAWYER, Knt., M.D., F.R.C.P. Lond., F.R.S. Edin., Consulting Physician to the Queen's Hospital, lately Professor of Medicine in Queen's College, Birmingham. Second Edition, Revised and much Enlarged. Birmingham: Cornish Bros. 1891.—The appearance of a second edition of this volume of medical essays, whilst it testifies to the popularity of the work, affords an opportunity of revising the original writings and of introducing two new essays—one on the treatment of gastralgia, the other on the use of ether as a menstruum in medication by the skin. The additions are quite in keeping with the rest of the work, being lucidly and agreeably written, and conveying much practical information. The volume affords excellent reading, and is well printed on good paper with a liberal margin.

The Pathology and Prevention of Influenza. By JULIUS ALTHAUS, M.D., M.R.C.P. London: Longmans and Co. 1892. — This *brochure* consists of the paper (amplified) which the author read before the Medical Society, and which was published in our columns. The argument, it may be remembered, was in support of a theory of influenza being due to a specific poison which acts especially on the nerve centres. There is much to be said in favour of this view; but we hardly think that the reasons adduced in support of the protective power of revaccination are convincing enough to be accepted. Whether we are destined to have another visitation of the disease or not, Dr. Althaus's contribution will remain as a clear exposition of some of the most striking of its phenomena, which may be helpful towards a truer conception of its nature.

The Hydropathic Establishment and its Baths. By ROBERT OWEN ALLSOP, Architect. London: E. & F. N. Spon.—This work contains a description of all the various kinds of bath employed by the modern hydropathist, the Turkish bath excepted, the author having treated that subject in a former work. This volume is addressed partly to architects and partly to the medical profession. The author hopes that "physicians of other schools than hydropathy will accord a not unkindly welcome to a work that at the worst may tend to promote that cleanliness which we are told is next to godliness." The practical requirements of the hydropathic establishment are fully considered and some existing institutions described. Vapour baths, the Russian bath, the douche, massage and electrical treatment, pulverisation, and the Mont Dore methods, inhalations, the "pine cure," the sun bath, &c., all receive adequate attention. Numerous illustrations and plans of the various forms of bath increase the value of the work. Into details of this kind we cannot enter, but we have tested Mr. Allsop's work at many points, and always with a satisfactory result. As regards the general system of hydropathy, the author remarks: "It is a great thing to rid oneself of the notion that baths of all kinds are merely aids to cleanliness of the visible portions of the human economy. Every bath has some therapeutic property, and this over and above its mere cleansing powers. In medical parlance, it may be derivative, stimulative, sedative, alterative, or tonic. The chief end of scientific bathing is to stimulate the functions of life by assisting the wasting of tissues and by aiding the recuperative and regenerative forces of nature."

California; its Life and its Climate. By AN ENGLISHMAN and AN ANGLO-CALIFORNIAN. London: W. W. Gibbings.—This anonymous pamphlet is meant mainly for intending emigrants, and deals chiefly with such topics as the cost of land in California, the cost of clearing the land, the products that may be grown, the price of labour, cost of building, &c. As regards the cost of living in California, we are informed that "beef and mutton cost 5*d.* and 6*d.* per lb. A whole salmon costs 3*s.* to 4*s.* Wine is cheap; an excellent claret can be had for 6*d.* per bottle. Oysters are cheap, and game may be had for the shooting. Groceries are somewhat dearer than in England." White labourers receive two dollars per day, and domestic servants about twenty dollars per month. As regards climate and health, the writers say: "Anyone who, for profit or for health, is seeking a new home might well consider the advantages and charms of residence in a land where roses, geraniums, and many other flowers bloom the whole year round, and where the climate is one eternal spring, whose enlivening and exhilarating sunshine and air send the blood coursing more briskly through the veins and lighten one's spirits."

"THE SMOKE NUISANCE."

To the Editors of THE LANCET.

SIRS,—The report of your Sanitary Commission on the smoke question is of especial interest at the present time, as a Bill, introduced by Lord Stratheden and Campbell, to give the vestries power to compel householders and hotel keepers to make some provision for the abolition of smoke, has recently passed the second reading in the House of Lords, and the Bill is supported—as for many years it has been—by the Duke of Westminster. Although London will always be subject to fogs, it is a disgrace to civilisation that no efficient legislative attempt has been made to eliminate the tons of soot held in suspension in the atmosphere whenever fogs appear. It has been suggested that the presence of soot may act as a germicide, and therefore, in a sanitary sense, may be beneficial. This suggestion is, of course, the greatest rubbish. The truth is that hundreds of lives are lost annually from bronchitis and other chest diseases as the result of breathing this irritating compound. Again, thousands of pounds are lost yearly through interruption of business caused by the black pall which often enshrouds London for days, and this great capital, which ought to be one of the finest cities in the world, has become a by-word of reproach and a place to be avoided during certain seasons. Again, our finest public buildings and statues become dirty and begrimed, and the whole city shows the impress of its murky atmosphere. I therefore venture to ask you to continue to lend the weight of your scientific research in assisting to pass the Bill which I have referred to. It proposes no drastic or impracticable measures. It simply confers powers on the vestries to frame regulations for the abolition as far as possible of this black scourge. I am quite aware that in the present state of our knowledge no definite plan of action can be laid down, but when it becomes illegal to poison the atmosphere with smoke I believe that before the dawn of the next century, now rapidly approaching, scientific research and practical experiment will do much to mitigate this scourge.—I am, Sirs, yours obediently,

THOS. BOND, F.R.C.S.,
Member of the Sanitary Committee of St. Margaret and St. John's, Westminster.

April 12th, 1892.

THE LANCET.

LONDON: SATURDAY, APRIL 23, 1892.

MUCH allowance is to be made for a Chancellor of the Exchequer who, finding himself unable to make any very satisfactory or startling announcements, tries to add to the interest of his budget statements vague and general reflections on the profitableness of particular professions or the wealth and comfort of their members. We are not disposed to be very hard on Mr. GOSCHEN for his recent and remarkable comparisons of the income of medical men and cotton spinners respectively and of lawyers and coal owners. We will let him off, but on one condition only—namely, that he shall descend to some rough particulars. We do not forget that before making these comparisons he had the wisdom to disclaim any intention of descending to detail. "I will not be so indiscreet as to place figures before the committee with reference to the aggregate profits of various trades and professions, but I have examined some of these proportions and they are most interesting." Mr. GOSCHEN thereupon made the famous statements about the lawyer in his quiet office and the doctor in his sombre study getting together taxable profits which do not make the outward show of the manufacturers, who employ a thousand men, but which, nevertheless, form a handsome and regular contribution to Schedule D. "The ubiquity and steadiness of these professions compensate for the lower scale of gain which they may be presumed to earn." Mr. GOSCHEN'S immediate justification for any such comparisons was in the argument that these happy incomes were independent of the vicissitudes of the general trade of the country, that whatever the suspension or abatement of the profits of the great manufacturers caused by strikes, or seasons, or fashion, or legislation, the gains of the professions went equally on as if they came from heaven. But we take leave to demur seriously to this proposition. The colliery surgeons could tell Mr. GOSCHEN differently—that while a strike rather increases their work, it stops their pay. It is self-evident that the incomes of the professions must depend largely on the general prosperity of the country, and it is certain that the incomes of medical men do eminently so depend. It is notorious that the medical man is the last creditor to be paid, that he is at everybody's call, and that he is supposed to be under some divine obligation to work without pay, or even the prospect of pay. The medical man's profits "ubiquitous and steady"! This reads more like satire than fact; but we shall forgive Mr. GOSCHEN if he will favour the House, and through it the public, with the real and the whole facts of the case. We know Mr. GOSCHEN to be a fair and just statesman, who would not willingly use his high position to injure or misrepresent any class of the community. We submit to him that in the unfortunate comparisons he has made he has done the medical profession great injustice. They will tend to make the public more than ever careless about their remuneration of medical men, and they will convey to them a most false impression of the wealth that is to be realised in it. That the whole profession makes a handsome and regular contribution to Schedule D only shows that the profession is conscientious in its returns. But it shows actually nothing of the general condition of its individual members. There are on the Medical Register of the United Kingdom 29,555 persons. Will Mr. GOSCHEN tell us what proportion of these pay under Schedule D; how many do not pay at all; and, roughly, on what sums they do pay? They themselves are ubiquitous. They live on mountains, on the sea, in remote villages, in the humblest parts of cities and towns, in the poorest districts. The income represented by Mr. GOSCHEN'S "handsome and regular contributions" has to be divided among all these persons, whose education has been costly, who have disproportionate expenses of living, and whose calling is perilous to life, and hard and exacting to a degree not true of any other calling. It is scarcely fair of Mr. GOSCHEN to tickle the ears of the public with statements so misleading. The poverty of the profession is abundantly testified. The State exacts much from medical men and it gives little. It exacts high education and high conduct. It affords them little or no protection. It gives them no prizes. It should at least refrain from misrepresentation of the very returns they themselves make. The income of a medical man often barely suffices for his current expenses, and it ceases with his uncertain and perilous life. It is a rare exception for him to leave anything that can be called a fortune. The average income of medical men is probably under £300 a year. It is from a profession so situated that Mr. GOSCHEN takes "handsome and regular contributions" with an air of satisfaction and confidence, and of which he speaks with flowers of rhetoric which excite laughter in the House. We venture to think that very different effects would have been produced if Mr. GOSCHEN had given the particulars of the case. The public is kept in the dark on these questions; it is entitled to more information. It should be possible to procure reliable data in detail from public offices, and it is to be hoped that some medical Member of Parliament will take occasion to ask Mr. GOSCHEN for the details we have indicated. Meantime let no misguided youth or his parent conceive of the medical profession as one even of the tributaries of the river Pactolus, to which anyone may come for the mere gold it will produce. It will yield many things: Work and care and even honour and self-satisfaction—but gold is not one of its rewards. The other features of the Budget need not detain us. We rejoice that the rush to alcohol has ceased. We rejoice in any proofs in the public revenue that the British workman has the unselfishness to abate his own huge expenditure on drink and even tobacco, before abating that on tea and other comforts of his wife and family. We cannot but regret that it is impracticable to reduce the burdens of public taxation, especially in the case of those to whom Mr. GOSCHEN confesses, in terms to which we must take the strongest exception, the obligations of Chancellors of the Exchequer.

WITHIN the last few months several very important coronerships have been rendered vacant by death. The first was that of the borough of Birmingham, which had

Digitized by Google

been held by the late Mr. HAWKESLEY, a solicitor, since the death of his predecessor, Dr. BIRT DAVIS, who held it for a period of thirty years. The hasty election which a literal compliance with the law would have involved was averted by the temporary election of the deputy coroner for the county up to a certain date, when he resigned, as had previously been arranged. Meanwhile, the respective merits and demerits of medical and legal coroners had been duly discussed, the result being the election of Mr. OLIVER PEMBERTON, our well-known *confrère*. Shortly afterwards the city coroner for Liverpool died most unexpectedly at the comparatively early age of sixty-four. The mayor, aldermen, and city councillors of Liverpool, having had no experience of medical coroners, and being evidently prejudiced in favour of a legal candidate, made the election in ten days and, according to the local press, on strictly party lines, the Conservatives supporting Mr. SAMPSON, the present coroner, the Liberals Mr. LYNSKEY. During the course of the election, however, Mr. F. W. LOWNDES, surgeon, received twenty-three votes. This was the only occasion—out of the three elections for coroner which have occurred in Liverpool since it became a municipal corporation—on which a medical candidate has received any support at all. Since then the respective merits of medical and legal candidates for the office of coroner have been fully and fairly discussed in two of the Liverpool daily papers, which circulate largely throughout Lancashire, Cheshire, and Wales. The ice, therefore, which was broken at the election has been dispersed in all directions, and it is gratifying to note that a legal coroner, Mr. THELWALL of Wrexham, has been sufficiently magnanimous, as well as right-minded, to elect for his deputy Dr. EDWARD DAVIES of Wrexham. This gentleman has for over thirty years made nearly all the post-mortem examinations for the present coroner, and given evidence in his court in a large number of cases. He has also been consulted by him in cases of doubt or difficulty in which the necropsies have been made and the medical evidence given by other medical witnesses. This recognition of Dr. DAVIES' peculiar fitness for the duties of the office is a good example which other legal coroners will do well to follow. Continuing the list of vacancies, we come to Chester, whose late city coroner, Mr. TATLOCK, a solicitor, died early in the year and was duly succeeded after ten days' interval by Mr. BRASSEY, solicitor. It is somewhat surprising that no medical candidate of sufficient standing and influence came forward to secure the support of the City Council, more especially as Mr. HENRY CHURTON, surgeon, who has held the office of coroner for the Chester district of the county for over fifty years, has during the whole of that time resided in Chester. Such an omission is probably explained partly by the short interval which elapses between the death of a coroner and the election of his successor, and partly by the greater influence which members of the legal profession often have with city councillors.

Another vacancy has now occurred by the death of Mr. W. CARTER, coroner for the Newington district of Surrey. For some time past he has been unable, from his great age and feeble health, to discharge the duties, which were accordingly carried out by his deputy, Mr. PERCIVAL WYATT. It is most desirable, in the interests of the public, that for this important appointment a thoroughly well qualified medical candidate should be found, that he should receive the loyal and hearty support of all his professional brethren, and through them that of the majority of the County Council with whom the election will rest. Of the 298 coroners in England and Wales whose qualifications are known—247 have legal—only fifty-one have medical qualifications. In other words, five-sixths of the English and Welsh coroners have no medical training, while those who have this most essential requirement for the office of coroner only number fifty-one, or one-sixth. How is this anomaly to be accounted for? The arguments in favour of legal coroners rest upon the flimsiest basis, which only requires exposure to show its utter hollowness. Many who support a legal coroner do so for the feminine reason "because they do;" this is at least the only reason they can give. Others give the more logical reason: because by the Municipal Corporations Act the deputy coroner must be a solicitor or barrister. But even this weak argument does not apply to coroners, either municipal or county, who both may be, and are, members of the medical profession. Nor does it apply to deputy county coroners, who may also be medical men subject to the approval of the Lord Chancellor. The last and strongest argument in favour of a barrister or a solicitor for the office of coroner is that he may be able to explain points of law, should these arise, better than a physician or a surgeon. But this argument will not bear the test of reasoning. Judges, recorders, and stipendiary magistrates are chosen from the ranks of those who have performed the routine duties of the courts in which they are subsequently called upon to preside, and a barrister can with confidence assume such judicial duties, he being in a sense "to the manner born." To try criminals or causes, to decide important points of law, these are essentially legal duties which any barrister may prepare himself to undertake eventually. The coroner's court is, however, totally different from any of the courts we have named. It is a court *sui generis*. The legal part might, according to Mr. WAKLEY, the first medical coroner, be learned in one day. According to Dr. LANKESTER, two hundred and ninety-nine out of every three hundred inquests involve no point of law, and the remaining one only points which a medical coroner can easily decide. A legal coroner necessarily comes to the duties of a coroner a veritable "fish out of water." The viewing of the body must be a mere form, and the technical medical evidence for the most part incomprehensible. Contrast this with an experienced medical practitioner, an old hand at attending inquests and making post-mortem examinations. The viewing of the body is to him an important medico-legal duty, for which he has been preparing himself ever since he first entered the dissecting-room years and years ago. Taking the evidence of witnesses upon oath as to the cause of any individual death is a simplified version of what he has been doing for many years past under much greater difficulties. The signing of burial and registrars certificates are quite in his way, while the oath administration to jurors and witnesses is so familiar to his ear from constant repetition that he scarcely requires to have the words before him. The office of coroner has always had its

Digitized by Google

quasi-medical aspect, but it will be greatly improved if it be regarded as a purely medical appointment. Why should not this be so?

The number of offices open to members of the bar, from that of Lord Chancellor down to that of Revising Barrister, is legion. Very numerous and lucrative also are the appointments open to solicitors from town and city clerks to those of clerks to the board of guardians. This office of coroner is the solitary one not absolutely medical which is open to members of the medical profession, and then only after a keen contest against a legal candidate. In Ireland and Wales the medical coroners are in greater proportion than is the case in England. Is it because the medical profession is more respected in the Principality and the Emerald Isle? When Mr. WAKLEY first held office he was the only medical coroner; since then his seat has been held by three medical successors, the legal candidate being in a minority on each occasion. Two other Middlesex coroners are medical men, and, as we have seen, the total number is just a unit over fifty. That which one man has done another man may do, and all that is required to secure these offices for the medical profession is that the profession should be true to itself and assert its claims. For every vacancy which is likely to occur a suitable candidate should be found ready against the surprise of a ten days' election. The chosen candidate should have the loyal and hearty support of all brethren. In this way we may hope to see each vacant coronership as worthily filled as was that for Birmingham a few months ago.

PROFESSOR CHRYSTAL'S graduation address on the 14th inst. at Edinburgh was memorable, not only in itself as a model of what such addresses should be, but also for the circumstances in which it was delivered, and for the remarks to which these gave rise. It was the last occasion on which the old Arts curriculum appeared on the academic stage before retiring in favour of its successor as framed under the new ordinance. As the representative of the superseded system, Professor CHRYSTAL could obviously have said more in its favour than he did—could have dwelt on the "excellent service" it had done, not only for Scotland, but for other parts of the empire, whose youth availed themselves fully of its advantages. But from this he wisely refrained, and passed on to forecast, in a prudent, but by no means pessimistic, spirit, the curriculum that is henceforth to take its place, until it in turn has to be modified or superseded by another yet more in harmony with the ever-changing requirements of humanity in evolution.

The Arts curriculum in the Scottish Universities owes its death to two causes: first, the increased efficiency with which at least three out of its seven subjects—Latin, Greek, and mathematics—are taught in the preparatory schools; and, secondly, the claims of other subjects to academic notice in lieu of the remaining four—logic, ethics, natural philosophy, and rhetoric. Young men now come up to the University with a classical and mathematical equipment almost equal to that with which the Bachelor or Master of Arts a generation ago left its halls; while the field of science has been so enlarged that it has forced in to the area of academic recognition subjects indispensable to the professional man in general and to the medical man in particular. Thanks to improved methods of teaching and improved text-books, the standard of proficiency in Latin, Greek, and mathematics with which the student now enters the University is so much higher than formerly that the time he used to employ in getting from the professor the knowledge he should have got from the schoolmaster he can now devote either to the prosecution of these subjects on a superior plane, or to the cultivation of others for which he has more aptitude, or which, with a view to his future profession, he can turn to better account. He can, if he chooses, become a better scholar in the old Arts subjects than he used to be; or, while possessing a higher proficiency in such of these as are still considered essential, he can select from the other subjects by which the Arts curriculum has been supplemented those which will be most useful to him in his calling in life. He can graduate in sciences which have a direct bearing on his professional career, and, if that be the medical, he can so train himself in these as to make professional study at once easier, more thorough, and more conducive to practical results. A great improvement this on the old system; but not without dangers of its own, to which Professor CHRYSTAL pointed significantly.

Now that pre-professional graduation has been made so much more profitable for professional after-study, will due advantage of it be taken? Will the future medical man be likely, in greater numbers than heretofore, to qualify himself for his career by graduation in Arts—in the improved curriculum now open to him? We hope he will, and Professor CHRYSTAL, with wise words, strengthens the hope. "I think," he says, "the tendency to press young men at once into the business of life is being overdone. It lowers the standard of the professional classes and it aggravates the block in these lines of life of which so much is heard, and which has irritated so many of our educational diseases to the stage of acuteness. Moreover, it is a mistake from the point of view of the individual, for I have noticed with satisfaction that of the few Arts graduates that now enter medicine, for instance, a very large proportion are to be found among those that ultimately distinguish themselves by success in their profession." But to attain this end—that of a more generally cultured, while more technically trained professional order—the qualifying bodies must coöperate; and the Universities themselves must not be tempted to relax the conditions of qualification so as to take in the "miraculous draught" for which some of them have been accused of lowering their nets. On this subject Professor CHRYSTAL might have enlarged with profit, but he contented himself with pointing to a real danger with which the new Arts Ordinance is fraught. As to its general principle, he declines to pass a criticism which experience might, on one side or the other, falsify. "It has been tacitly agreed on all hands," he says, "to give it a trial. I cannot, however, refrain from saying that, after mature consideration, I have come to think that it is of doubtful educational soundness, in so far as it sets up a kind of competition by Dutch auction between the kindred subjects of the old departments. There will, I fear, be a tendency in

Digitized by Google

the future for passmen to crowd, not to the better or more thorough teacher, but to the more popular subject and the easier-going professor. This will be seen in all the compulsory departments, and in the optional subjects to some extent also." This is a very real and not very tractable danger—so much so that the University Commissioners are, in answer to authoritative representations, devising means by which it may be met. After all, no innovation, however well considered, works with unexceptionable smoothness in its early stages. Experience comes in to correct, modify, and adjust, till drawbacks, suspected or unforeseen, are replaced by better working conditions. Manifold, indeed, are the influences which may be counted on to perfect the academic machine—influences like that spirit of emulation which forms the motive power of all improvement. Edinburgh, even under her extended Arts Ordinance, will never be allowed to forget that she has rivals in the academic field whose efficiency she must cope with, and whose advantages she must counterbalance or outweigh, if she is to maintain the position she has long held as a centre of culture and of professional qualification. It is this honourably competitive spirit her University Commissioners must practically recognise if the not illusory dangers foreshadowed by one of her ablest representatives are to be averted or avoided.

TIME and again this unwieldy piece of legislation, with its 563 clauses, has been before Parliament in the course of the past decade, and as often its admission to the Statute-book has been deferred. The House of Commons will consider the sanitary clauses of the Bill on Monday evening next. In the best interests of public health in Scotland, it is to be hoped that it will meet with its previous fate, or else that the clauses in question will be entirely dropped. Should it pass in its present form, then, as is pointed out in a memorandum issued by the Scotch medical officers of health, Scotland will be in the remarkable position of having two sets of sanitary laws running concurrently—one in the burghs and the other in the rural districts. The former would be under the new Act, and the latter under the Act passed in 1867. It has been suggested in some quarters that the passing of the Local Government Act of 1889 is a reason for withdrawing the objections which sanitarians in and out of Parliament have always felt to the Bill. As a matter of fact the opposite is the case. The counties have now been compelled to appoint medical officers who have to devote all their time to their duties, and surely they have a right to share in any improvements in the sanitary legislation of the country. But it is proposed instead that the new law should be handed over to the local authorities of small burghs who pay their medical officer perhaps £5 a year, while those authorities who have had to appoint skilled and practised officials are to be left with a law in which the chief interest ought now to be felt by the antiquarian. It may be urged that there is no harm in giving the burghs this year that which the counties might get next year. But the *crux* of the case is that giving to the burghs now will delay indefinitely the meeting of the requirements of the counties in the future. It is the burgh members who are anxious to pass the Bill, and if once their constituents are satisfied, it will be many a day before Parliament finds time to attend to the needs of the remainder of Scotland. Surely it would be better, as the Society of Medical Officers suggests, that the Infectious Disease Prevention Act, 1890, and the Public Health Amendment Act of the same year, both of which refer only to England and Ireland, should in the meantime be extended to Scotland, both urban and rural, and that when other legislation is undertaken it should consist of a Public Health Act which would embrace the country as a whole.

It is not our purpose to criticise the various clauses of the Bill as it stands. But if it were desirable that they should pass at all, there would be abundant room for amendment. The provisions with regard to the notification of infectious diseases are in several respects different from those of the Notification Act which is already in force in many of the burghs, as well as in nearly all the county districts. Under the Bill, notification may be made either to the medical officer or sanitary inspector, and to give any such choice in regard to such a matter is, on the face of it, absurd. Medical men are to be paid for notification, "unless it be found that the diagnosis of such practitioner was incorrect." What relations are likely to be set up between three or four medical men in a small burgh when the local authority insists on one of these practitioners revising in every infectious case the judgment of his brethren? Then, again, we find the astounding provision that notification is to extend to "every case of infectious disease *and whooping-cough*." When the local authority of Dreepdaily gets in its first account for a whooping-cough epidemic, it will begin to wonder whether the new Act is not more expensive than useful. And it will no longer have any doubt on the point when it realises that the Act compels it to provide hospital accommodation for its population of 700 or upwards, and at the same time gives it no power to unite for this purpose with the surrounding county district, but only with other burghs which may be many miles away. Section 367 seems expressly drawn up for the purpose of causing friction between burghal and rural sanitary authorities. "Whenever it shall be certified by the medical officer of health ..... that milk is being brought within the burgh from any farmhouse, dairy, or place beyond the burgh in which any person is ill of infectious disease ..... the burgh prosecutor or sanitary inspector shall apply to the magistrate for an order to prohibit the sale of milk so bought," and so on. Surely the supervision of infectious disease in dairy farms might safely be left to the medical officers of the county districts in which the farms are situated. It is true that previously to the passing of the Local Government Act the city of Glasgow obtained powers of this kind by a local Act, but the circumstances are entirely altered now. In the case of a dairyman selling milk—say, in three burghs—the effect of the clause in question would be to place him under the power of no less than four local authorities—those of the three burghs and that of his own district,—and these possibly with divergent views as to the proceedings required to be taken in the presence of infectious disease.

The Bill bristles with objectionable clauses, but space forbids our giving more than the above examples. It is

Digitized by Google

significant that no single medical voice in Parliament has been raised in its favour, and that it is receiving, at least as to its public health provisions, the active opposition of Dr. CLARK and Dr. CAMERON. It is sincerely to be hoped that their opposition will be successful.

Annotations.

"Ne quid nimis."

THE MEDICAL OFFICER OF THE LOCAL GOVERNMENT BOARD.

WE congratulate Mr. Ritchie, the President of the Local Government Board, on his appointment of Dr. Thorne Thorne as the successor of Sir George Buchanan, F.R.S. The wisdom of the appointment of Dr. Thorne as head of the department with which he has been so long and worthily connected will be ratified by the opinion of the medical profession and the public In addition to his long and varied official experience, Dr. Thorne has made his mark by much excellent and original etiological work. He is a Fellow of the Royal Society, a Bachelor of Medicine of London University, and Fellow of the Royal College of Physicians of London, Honorary Member of the Academy of Rome, Lecturer on Public Health at St. Bartholomew's Hospital, and Examiner in Public Health for the Universities of Oxford and London. Dr. Thorne was President of the Epidemiological Society, and was a British delegate to the International Society Conference at Rome in 1885, where he did excellent service. His connexion with the London Fever Hospital and the Royal Hospital for Diseases of the Chest has given him a practical acquaintance with disease and hospital work. Dr. Thorne is well known as the author of various official reports on public health and cognate subjects, one of which we may mention—namely, that on the use and influence of hospitals for infectious diseases. His Milroy lectures on Diphtheria, its Natural History and Prevention, attracted much attention, which was well merited. There is therefore abundant evidence of Dr. Thorne Thorne's qualifications for the post as far as technical and professional culture are concerned, and he has besides the reputation of possessing the tact and good judgment which are so necessary in a public official who has always responsible, and sometimes difficult and delicate, duties to perform.

A TEACHING UNIVERSITY FOR LONDON.

WE have strongly urged on the Government the necessity of appointing one or more eminent medical men to serve on the reconstituted Royal Commission which is now being formed for the consideration of this highly important matter. The question of degrees for London medical students obtainable on conditions similar to those existing in the other centres of medical education is so intimately connected with the wider aspects of university teaching in London that it is quite imperative that representatives of our profession should be included among the Royal Commissioners, and one of the blots in the constitution of the former Commission was the non-inclusion of any such representative among its members. At the same time it is obvious that in such a selection, past and present teachers who have taken a decided line either for or against any of the schemes which have been brought before the Commission or the Privy Council should not be asked to serve, nor should any member of the Senate of any of the other universities which would be affected by a solution of the problem, be selected. The difficulties can only be rightly weighed and estimated by an absolutely impartial and judicious investigation, and it is only by eliminating all persons who might be considered in any sense to have a partisan view that this can be secured. We trust therefore that the rumours that some members of the deputation which waited on Lord Salisbury (in opposition to the Charter of the proposed Gresham University) will be placed on the Commission are incorrect. Sir William Savory and Sir George M. Humphry have been mentioned as the probable medical representatives, but it is obvious that these eminent members of the profession are too closely concerned with two of the bodies which have already taken action in the former phases of the problem to be in these respects fit and proper representatives. Sir W. Savory has served throughout on the Joint Committee of the Royal Colleges which propounded a scheme which was rejected by the Commission; and Sir G. M. Humphry is an active member of the University of Cambridge, which also presented a petition to the Commission, which was taken into consideration. It can surely not be difficult to find members of our profession, not connected with the governing bodies of any of the universities or corporations which have already taken action in the matter, whose position and judgment would carry due weight. From every personal standpoint, and on any other Commission in which medical interests are involved, no more suitable members of our profession could be chosen than the above-mentioned gentlemen.

EGYPTIAN MEDICINE.

So rapidly is our knowledge of ancient medicine increasing that already the chapters devoted to it in such standard works as those of Häser and Puschmann are getting out of date and will have to be rewritten, or at least revised. Chinese medicine, for example, perfunctorily handled by the former of these historians, and completely ignored by the latter, is, thanks to the research of the medical missionary, becoming better known to us every year. Indeed, within the last few months the historico-critical studies of Dr. J. Berendes, one of Germany's most scholarly pharmacists, have shown us how rich was the Chinese materia medica in remedies not a few of which might be profitably reconsidered with a view to their employment in nineteenth-century therapeutics. But it is Egypt that impresses us most profoundly with the wealth of surgical and medical resource enjoyed by her ancient practitioners; and, now that we are on the track of so much literary treasure-trove in papyrus, we may look to the same discoveries that have given us Aristotle's Constitution of Athens and the Mimiambi of Herondas for yet further accessions to our knowledge of how men fared at the hands of the profession in the great Nile Valley millenniums before Christ. The "Papyros Ebers: the oldest Book on the Healing Art," is now a κτῆμα ἐς ἀεί, not only in its original form, but in the singularly painstaking and circumspect translation of it by Dr. Heinrich Joachim of Berlin. To this we shall take an early opportunity of returning; but meanwhile we may draw the reader's attention to another and quite recent discovery in the same prolific field. M. Bouriant, a member of the French Egyptological School of Cairo, in a memoir read before the French Academy, has for the first time given to the world "A Fragment of an Egyptian Medical Work," preserved in Coptic in the so-called Theban dialect. Other portions of the manuscript to which this fragment belonged would, it was hoped, have been discovered, but hitherto the search for the missing portions has been unsuccessful. What we do possess is a strip of parchment, forming one leaf of a manuscript, and con-

Digitized by Google

stituting pages 214 and 215 of the same. Zoega, in his "Catalogus Codicum Copticorum," mentions four pages of a similar work; but these have not yet been published, and so M. Bouriant's translation of the fragment he himself has found possesses an interest still unique. That translation (into French) is too long to be given here *in extenso*. Suffice it to say that it treats of the female mamma in health and disease. In the former state, when a flow of the lacteal secretion is sought, special drinks and applications are prescribed; and in the latter, when the breast is sore, cataplasms of various kinds are recommended. These bear a strong family resemblance to those already known to us from the "Papyros Ebers" and the historico-critical researches of Berendes; but a specimen in M. Bouriant's French has an interest of its own. "Pour les seins endoloris—s'emploie aussi pour le corps mâle de l'homme—prends la plante nommée 'œil de chat,' de la ceruse, de la litharge, du plomb, et de l'opium en quantités égales; broie-les bien; ajoute un peu de vinaigre; mets (le tout) dans du suc de jusquiame; fais cuire dans du suc de vigne femelle; mets dans un vase du plomb et laisse reposer; frottes-en les parties malades jusqu'à la guérison." Other indications are given as to how to keep this medicament in readiness for use from time to time. The other prescriptions are not less curious, and certainly whet our anticipation for still further additions to what we know of Egyptian medicine. M. Flinders Petrie, we are aware, brought to England recently a portion of a very ancient papyrus containing a book on veterinary medicine, dealing specially with the eye diseases of oxen. This, when translated, cannot fail to be interesting, and will, we hope, lead to yet further discoveries in the veterinary art of the Egyptians, particularly their mode of treating cattle plague on an epidemic scale.

DEATH OF DR. ALLON.

WE cannot but join our contemporaries in a note of grief at the death of the Rev. Henry Allon, D.D., of Islington. Dr. Allon was more than the representative of a leading dissenting body. He was in touch with all religious bodies in that general coöperation for good which is their chief credit. One of the last characteristic public functions he discharged was to fill the chair, after it had been vacated by the Archbishop of Canterbury, at Lambeth Palace, at a meeting for providing summer holidays for poor children. He was from the beginning a promoter of the Hospital Sunday Fund in the Metropolis, was a member of the council of the Fund, was on its General Purposes Committee, and was in every way one of its best friends. He was an effective and dignified speaker either in or out of the pulpit, and was held in high respect by all the earnest men of his time even when they differed from him in opinion.

THE PRACTITIONER'S PARASITES.

FEW medical men of any standing have not experienced at some time or other the importunities of the begging impostor. Now as a poor but unfortunate fellow countryman, now as an invalid, as a dispenser out of work, as a brother practitioner in monetary difficulties, or as representing one of a dozen other phases of distress, he is constantly turning up. He is affable, voluble, pitiable. He comes laden with manuscript recommendations, yet he is evidently devoid of credit. Like the rich, he, though poor, has many friends, and they too as needy as himself, and as willing to avail themselves of the charity which he first scented out. His name is legion, and his modes of "working," as we have seen, show him to be quite a social chameleon in adaptation. We may briefly notice, by way of illustration, two specimens of this class who were charged a few days ago at the bar of Worship-street Police-court. This couple, a husband and wife, were in the habit of utilising the name of some former student of a medical school, supposed to be in bad health and poverty, in order to extract from one or other of his quondam teachers a solid proof of their esteem or pity for him. The appeal was, of course, by letter, and for a time was not wanting in success. Its ultimate consequence, as might have been expected, was their appearance in court. We may hope also that this exposure of their method may convince the less cautious of our medical brethren that a searching investigation is a needful and by no means unhandsome preliminary to the exercise of their generous compassion.

SAD DEATH OF A MIDDLESBROUGH CYCLIST.

OUR Newcastle correspondent, in his letter this week, notes the sad death of a young man aged twenty-two, belonging to Middlesbrough, who had ridden forty miles before he was taken ill on Good Friday last at Great Ayton, in Cleveland, where he died the next morning. The cause of death is said to have been syncope brought about by cold and over-exertion. It appears that this young man was a practised bicycle rider, and to such forty miles could hardly be considered an excessive run in a day; but, besides distance, many things have also to be considered by the judicious rider—for instance, the nature of the roads, the weather, and, perhaps above all, the pace. We know that the new machines are capable of attaining a speed never thought of a few years ago. A high speed through cold air such as prevailed on Good Friday must often be very dangerous, as likely to cause pulmonary congestion, to overcome which the heart will work at a high degree of tension, and, like any other muscle, it is likely to become paralysed from overwork; and herein lies the danger from swift and hard riding. It would be well if our young men would remember the advice that an eminent English physiologist gave to a young man some years ago: "Observe your strength, and keep within it."

QUARANTINE AND ISOLATION AT BARBADOES.

THE Board of Health of Barbadoes have erected a hospital for infectious diseases on Pelican Island, the cause of its erection having been one of those difficulties attaching to the inhuman practice of quarantine when that system is carried out on old-fashioned principles, which, we trust, few would now advocate. According to the *Barbadoes Herald*, the hospital is the outcome of the sad fate of a large number of the crew of the barque *Mozart*, who, one after another, were taken with yellow fever, there being at the time no place whither the hitherto healthy seamen could be removed so as not to be exposed to the infection of their sick shipmates and of the infected vessel itself. But now that the hospital has been provided, the authorities are confronted with a new difficulty. If the hospital is to be generally available for all infectious sick arriving by sea, it is feared that masters of vessels will be careless as to taking infection on board, for they will be able to land them at Pelican Island, where considerable aggregations of the infectious sick may thus occur. The authorities seem to fear that if this takes place danger will arise for the inhabitants. But, apart from aggregations of small-pox in contiguity to inhabited localities, we doubt whether any such hospital as is likely to be provided on Pelican Island stands much chance of doing harm in this way. A somewhat similar difficulty has arisen in our port sanitary districts. Captains and masters of vessels, knowing that at a certain port a hospital exists, enter that port and expect to have cases of infectious diseases taken off, so that they may proceed on their journey without risk. The difficulty with us has been mainly a financial one, for southern ports, for example, do not care to be burdened with the cost of

Digitized by Google

isolating and maintaining the infectious sick whose destination is London or some other port; and one at least of them has demanded that if they are expected to perform what they term imperial health functions, the State should pay the cost. The attitude is one by no means easy to meet. Every district, in a certain sense, protects others as well as itself, and the line between local and imperial work cannot be drawn in as simple a way as some imagine. But it ought to be possible to charge upon owners of vessels the cost incurred in the removal of the infectious sick from their vessels and in subsequently maintaining them. As yet the patient, who is often a poor sailor, can alone be charged. The Barbadoes question may eventually be solved on some such lines, for it is not likely that, having provided a hospital because of the disaster on board the barque *Mozart*, they will ever run the risk of a similar occurrence so long as beds are available on Pelican Island.

ADMISSION OF MINISTERS TO ISOLATION HOSPITALS.

A DIFFICULT question in Guildford has been raised by the Rev. Reginald Fowler—namely, the right of a Roman Catholic priest or any other minister to visit his people at any time while they are inmates of an isolation hospital. He not only maintains the reasonableness of this rule, but gives letters from the authorities of the Metropolitan Asylums Board and other institutions to show that any clergyman wishing to visit a patient would be admitted. Mr. Fowler writes to the *Surrey Advertiser* complaining that he has been informed by the medical officer in charge that he cannot be admitted to see patients unless they are on the point of death and by his permission. The question is a delicate as well as a difficult one. The committee of the isolation hospital support their medical officer and defend their rule. One remark is obvious, that the question raised is not one of liberty of conscience at all; liberty of conscience is not invaded in the least. The Catholic patient has his Catholic priest, and the Protestant patient has his minister according to his own choice. It is simply a question of expediency. The object of an isolation hospital is isolation—namely, the reduction of the chances of conveying infection. The priest should be admitted whenever necessary, but not unnecessarily. The medical officer should not be rigid in sanctioning the visits of ministers of religion. On the other hand, ministers of religion should not expect the same liberty to visit in an isolation hospital which they have in a private house. Their visit may carry risk to outsiders, it may be injurious to the patient himself, and it may disturb other patients. According to our view, the medical officer of a public institution and the minister of religion should consult together in this matter, and should have no difficulty in safeguarding the interests of all the patients.

A CASE OF SYPHILITIC REINFECTION.

THE following interesting account of what would seem to be an undoubted case of syphilitic reinfection is published by Professor Alexis Pospelow of Moscow. A patient, towards the end of October, 1882, fourteen days after exposing himself to the liability of syphilitic infection, noticed a sore of the size of a lentil in the sulcus behind the glans penis. He was seen by Professor Tarnowsky, who diagnosed a hard chancre, and ordered the local application of mercurial ointments. On Dec. 20th a well-marked eruption of syphilitic roseola appeared on the body, and, there now being no doubt as to the correctness of the previous diagnosis, he was placed under treatment by mercurial inunction. Shortly afterwards mucous patches appeared on the fauces, mouth, and lips, for which iodide of potassium was prescribed; but this produced such violent diarrhœa that its use had to be discontinued. The mercurial treatment was kept up until the end of March, when the rash and ulceration of the throat had disappeared. However, in May he had a troublesome attack of palmar psoriasis, for which he was recommended to resume the inunctions, and to visit the sulphur baths at Piatigorsk in the Caucasus. Upon his return to Moscow three months afterwards, no trace of his former attack could be found. In spite, however, of this freedom from symptoms, he spent the summer of 1884 at Piatigorsk, and resumed the mercurial treatment. In the autumn he again returned to Moscow, and remained under supervision for the next two years. As there was during this period no appearance of any relapse, he was given permission to marry, which he did in 1886. Nine months afterwards a healthy child was born, and both the mother and infant remained in good health during the whole period of lactation. Subsequently he separated from his wife in consequence of matters not connected with his health, and remained so for three years. Unfortunately, towards the end of this period he again ran the risk of infection, and contracted a double chancre at the root of the penis, followed by sore-throat and roseola. The case was seen by several medical men, and was considered to be undoubtedly one of reinfection.

THE PROFESSION IN WALES AND THE GENERAL MEDICAL COUNCIL.

AT the North Wales Branch of the British Medical Association a resolution was unanimously passed approving the principle of a direct representative for Wales in the Medical Council. Mr. Jones Morris pointed out that there were only 800 medical men in Wales, and said it would be somewhat puerile to agitate for a Welsh representation. But Mr. Richard Williams of Liverpool urged the consideration of the question from "a national" point of view, and this naturally carried a Welsh meeting. Put in the form of a problem of mere numbers it could scarcely be seriously argued. For these 800 gentlemen to have one direct representative all to themselves and the 18,000 of England to have only three would obviously be a greater anomaly than the present joint and equal representation of England and Wales. We commend this aspect of the question to our Welsh readers.

GENERAL PARALYSIS IN A BOY.

IN the *Archives de Neurologie* for March an interesting case, apparently of general paralysis of the insane, occurring in a youth of sixteen, the first manifestations of the disease having been at the age of fourteen, is recorded at length by MM. Charcot and Dutil. The boy had been bright and intelligent at school, and had had no previous illness of any significance. He was one of a numerous family, eighteen in all, and of these he was one of three survivors. His father was alcoholic, and had had an attack of alcoholic delirium soon after the boy was born. His family and personal history otherwise presented nothing noteworthy in respect of neurotic tendency. When he came under observation he was found to look younger than his age, the marks of puberty being little apparent, as if his physical development had undergone a somewhat sudden arrest. He had the characteristic, uncertain, awkward gait, but he showed fair capacity for attention to questions. He was, however, manifestly feeble intellectually, and his memory was notably impaired. He also had tremor of the tongue and lips and difficulty in articulating, while the tremor in his hands was marked, and his writing was characteristic. The pupils were unequal, and he was subject to attacks of peculiar sensations in different parts of his limbs, chiefly on the right side. In one such attack

Digitized by Google

there was well-marked interference with speech function. No exalted ideas were present, but the case presented so many other characteristic features as to leave little doubt that it should be placed in the category of general paralysis occurring at an unusually early age, like several cases already recorded in this country and in France. With reference to the age of incidence of general paralysis of the insane the opinion of Mickle is quoted—viz., that the age at which general paralysis develops nowadays is an earlier one than it was formerly, and that this is the result of a premature senility among individuals, and is a precursor indicative of the decadence of the race. But, perhaps, as is suggested in the paper under notice, it is really a result of our being now able to diagnose the condition when its signs are much less manifest than they had to be before the disease could be recognised in past times.

LADIES' DRESSES AND CONTAGION.

WE have already (THE LANCET, Aug. 22nd, 1891) had occasion to notice the supposed influence of the trains of ladies' dresses in spreading contagion. The matter has been warmly taken up in Vienna and Pesth, and we now learn that a regular crusade has been instituted by the Sanitary Board of Hungary against the obnoxious fashion. It is not to be expected that the justice of this course will pass unquestioned. By very many persons it will certainly be regarded as an instance of the mere enthusiasm of sanitation, having but the slightest foundation in reason or science, and as little connexion with practical cleanliness. There is some room for argument on both sides, nevertheless. Granted that the germs of disease abound in a given quarter, no ordinary means could more effectually ensure their dispersion than the broom-like action of a flowing skirt. On the other hand, it is to be remembered that this very movement implies an admixture of air and oxygenation of the dust-cloud. Then, again, one is tempted to inquire whether a reduction of the length of train is the best method of dealing with this question of germ dispersion by means of street dust. Would it not be better, in combating whatever contagion may linger among its particles, in spite of a purer surrounding air and sunlight, to rely upon the sanitary water-cart or hose and the scavenger's brush? If dress fashions are to be held responsible and forbidden, are the whirl of traffic and the bustle of hurrying pedestrians, though they wear no trailing robe, to be restrained also? We admit a cordial dislike to this latter garment, both on account of its close and clinging unwholesomeness as regards the wearer and on the ground of its public inconvenience. Nevertheless, the surest remedy for infection by means of dust is, in our opinion, rather to be sought in the cleansing of thoroughfares than in the restraint of fashions in dress.

PATHS IN THE CORD.

IN the recently published number of *Brain* an abstract by Dr. David Inglis of Detroit is given of a paper by himself. The paper was read before a meeting of the American Neurological Association, and had for its subject Friedreich's ataxy and its relation to the conducting paths of the cord. Taking Friedreich's own summary of the characters of the disease, in which it is described as a progressive paralysis of the faculty of combination of movements, he reviews the conditions found in the thirteen recorded necropsies. These are a progressive sclerosis always affecting the columns of Goll, also the column of Burdach, but not so completely, and the direct cerebellar tract, with Clarke's column in most, and the crossed pyramidal tract in some cases—that is, the disease is one which affects chiefly the tracts which degenerate upwards. It should be stated, however, that Dr. Inglis does not mention the direct pyramidal tracts, which are certainly degenerated in some cases. He contends that the symptoms of Friedreich's ataxy afford a demonstration that those tracts do not convey sensory impulses upward, for sensation is not impaired, but that they are the main tracts for the conveyance of coördinated motor impulses downward; that their anatomical relations with the medulla, cerebellum, and mid-brain, as well as the facts of Friedreich's disease, agree in showing them to act in coördinating motor impulses of the mid-brain, cerebellum, and higher and lower levels of the cord. The facts of embryology are also claimed as strengthening the theory; for it is stated that the infant is characterised not by voluntary control of its muscles or by accuracy of sense perception, but by an extensive coördination of involuntary motor functions, and that at this time the posterior columns and direct cerebellar tracts are fully developed, while the pyramidal tracts are still undeveloped. Further, it is stated that the direction of Wallerian degeneration is not necessarily the same as the direction of normal physiological impulses in any given tract.

HEALTH OFFICER FOR THE COUNTY OF NORFOLK.

A SPECIAL COMMITTEE has been appointed by the Norfolk County Council to consider the question of the appointment of a county health officer. One of the principal reasons given for this is the need of support to local health officers who have reported as to the housing of the working classes, and the mover of the resolution pointed out that such officers were some of the worst paid in England. A paltry remuneration for health purposes has undoubtedly at times had its cause in a desire that but little should be done which would involve cost to house and cottage owners. But there are happily many ill-remunerated local health officers who are doing their duty in the matter of the housing of the poor, and in Norfolk such officers would doubtless welcome the support of a supervising county officer.

THE HEALTH LAWS OF THE BIBLE AND JEWISH LONGEVITY.

THE *Asiatic Quarterly Review* of January contains a report of a paper on the above subject, read before the Oriental Congress by Mr. Marcus N. Adler, M.A., F.S.S., Fellow of University College, London, in which are set forth in compact form some of the more important points of the Mosaic law which have a bearing on the health and longevity of the Jews. There are certain statements with which those who have studied the subject will not agree; but, on the whole, we find in this article a very compact *résumé*, which, to most minds, will be perfectly convincing. It is difficult to understand why the quantity of gelatine that "pig meat" contains should be selected as one of the points to indicate its special unsuitability for food, "gelatine being a favourite nutriment of morbific bacilli"; most of those who have attempted to cultivate morbific bacilli in "pure" gelatine find that it is a very bad medium. It requires to be specially prepared and diluted before it is of much value. The part it plays in solid culture media is purely mechanical. Then, too, actinomycosis, which is here quoted, can scarcely be looked upon as a disease which leads to much infection amongst human beings. A very interesting part of the paper is a table drawn from the American returns, in which is given a comparison between the death-rate amongst Jews and that amongst the general population from phthisis, diabetes, and diseases of the spinal cord, and also of the number of the insane amongst people similarly classified. The figures are as follows: From phthisis the mortality amongst the Jews per 1000 was—males 36·57, females 34·02; whilst amongst the general population it reached—males 108·79, females 146·12.

Digitized by Google

From diabetes, Jews per 1000—males 19·85, females 19·59; and the general population—males 2·74, females 1·21. From diseases of the spinal cord, Jews per 1000, males 9·40, females 6·18; general population, males 3·73, females 3·32. Although these diseases, spinal complaints and diabetes, have such an important influence on the mortality of the Jews, and are supposed to arise principally from nervous and mental strain (to which the exhausting business pursuits and head work of the Jews are supposed to subject them), the number of insane amongst them is only 44·5 per 100,000 of population; whilst amongst the general population of the United States it is 336. Mr. Adler sums up that Jewish longevity, fertility, and immunity from certain diseases cannot be looked upon as specially racial; he considers that they are due to moral and religious influences and are the outcome of Jewish habit, education, and environment; and he further maintains that these advantages will endure as long as such influences are permitted to operate, but that they must disappear, as to some extent they are disappearing, where the bonds of religion and traditional laws are relaxed.

THE COBWEB AS A STYPTIC.

WHEN Bottom was "translated" and introduced to the attendants of Titania, he endeavoured to ingratiate himself with Good Master Cobweb by saying, "When I cut my finger I will make bold with you." To arrest bleeding the application of a cobweb to the wound has long been a rural custom. Experience has shown that the gossamer of which the web is composed forms a very useful styptic; but a very fatal objection to its use arises from the fact that as an application to an open wound it can never be guaranteed to be surgically clean, forming as it does a net for insects, and at the same time for the germs of many an infectious disease. Evidence of this was produced before the Liverpool coroner recently touching the death of Martha Roberts, who, following the time-honoured custom, had applied a cobweb to her wounded hand to stop the bleeding. Blood poisoning followed upon its application, and this terminated, unhappily, in a fatal issue. It is not a solitary case. The principles of asepticism have not yet become part of the intellectual equipment of the people, neither have its lessons succeeded in overcoming prejudice.

GASTRIC ACTIVITY IN INFANTS.

M. VAN PUTEREN has made a long series of examinations of the digestive process in infants. A summary of the results of experiments made on 248 healthy infants is given in the *Boston Medical and Surgical Journal* of March 10th, 1892. The following points are noted:—1. After a meal of from sixty to eighty grammes of milk the stomach may be readily pumped out after an hour and a half, but the quantity ejected rapidly diminishes during the first hour. At the end of two hours only from twenty to thirty cubic centimetres may be obtained, and this disappears slowly in the course of half an hour. 2. The acidity of the infant stomach is much less than that of the adult stomach. This was tested by neutralising with one-tenth normal soda solution, using phenolphthalein as an indicator. The average results showed an increase of from 0·03 to 0·038 per cent.—that is, from 0·3 to 0·9 parts in 1000—for digestive periods of from ten to ninety minutes, after which no increase of acidity was apparent. The lowest acidity observed was 0·022 per cent., while the highest (0·121 per cent.) was only a half or a third of the amount considered normal in the adult. The determination of the character of the acid met with some difficulties, since many of the more usual colour reactions are uncertain in digesting mixtures of such feeble acidity. By the use of more exact methods M. Van Puteren convinced himself that hydrochloric acid is the normal acid in the infant stomach during the first two months, lactic acid being only exceptionally present. 3. The anti-fermentative action of the gastric juice seemed to be exceedingly feeble. Plate cultures made at successive periods of the digestion showed no marked difference in the number of colonies. The conclusion arrived at is that the gastric juice of the infant is not very efficient as a germ destroyer, and the infantile digestive organs are therefore particularly prone to disturbances, which, however, may for the most part be prevented by the use of sterilised milk. 4. The milk-curdling ferment (rennet) was always absent in infants up to twenty-four days, and could only be definitely demonstrated at thirty to forty days of age. M. Van Puteren's results as to the peptonising power do not seem sufficiently exact to be interesting. Albumen (by which is presumably meant a substance coagulable by heat) has generally disappeared by the end of the first hour, and peptone is constantly present twenty-five minutes after feeding and until the end of the digestive process. Sugar was always found, and fat also, so long as peptone was present. Free fatty acids (as the result of a fat splitting ferment, or of the similar action of the pepsin hydrochloric acid) could not be found.

THE DURHAM STRIKE AND MEDICAL MEN.

THE *Newcastle Daily Journal* has some very pertinent remarks on the hard case of the medical men in the pit districts. The miners who so light-heartedly continue their ruinous strike do not the less need medical attendance. On the contrary, disease is apt to assert itself in more serious forms under the conditions of a strike, and the colliery surgeon is expected not to strike. The inconsistency of human nature is well illustrated here. The miner would be appalled if his medical man struck, and declined to answer a summons to a fracture or a confinement. There are classes of men who on simple grounds of humanity do not strike, and yet attend to those who do. But they are all the more entitled to have a clear understanding with the miners as to their reward when the strike is over. A correspondent of the above-named journal suggests that the miners should agree to a deduction of 6*d.* a week from their wages when work is resumed till the debts are paid. The proposal is a reasonable one, and no honourable miner will refuse to agree to it.

THE REPORTED DISCOVERY OF THE MEASLES BACILLUS.

DR. CANON and DR. PIELICKE, of the Moabit Hospital, the former of whom was one of the first to demonstrate the presence of the influenza bacillus in the blood, have now turned their attention to measles, and it is reported (as will be seen by reference to our Berlin correspondent's letter) that they have been so far successful that they have been enabled to demonstrate the presence of a specific bacillus in connexion with this disease. This discovery has naturally attracted considerable attention; for although *a priori* we should expect measles to be the result of the action of such a germ, we have hitherto been unable to associate it directly with any such causal agent. In fourteen patients they have succeeded in finding what they assume to be a specific bacillus in the blood, in the expectorations, and in other secretions. This bacillus is stained with methylene blue in the same way as the influenza bacillus, the colouration being specially intense at the ends. The different individuals differ considerably in length, being from $\frac{1}{3000}$ to $\frac{1}{1000}$ of an inch. Its characteristics are said to be different from those of any other bacillus known, and artificial cultures have already been obtained. If once we are enabled to study the life history of this organism, there seems to be a possibility that we shall be able to take some efficient

Digitized by Google

steps in the protection of children against this disease. The further observations on this organism and on its power of producing the disease will be awaited with additional interest from the fact that it appears to be so like the influenza bacillus in its distribution, and also to a certain extent in the effect it produces, in spite of the fact that it is very different in structure and appearance from the influenza organism. We hope that this is not another cry of "Wolf," unless it be the final one.

DENTAL LECTURES AT HASLAR HOSPITAL.

AT length something has been done to give some instruction in dental surgery to the medical officers of the navy, and we heartily hope this will be a forerunner of a similar step with regard to the army. Surgeon Herbert Canton has been appointed to the *Victory* for Haslar Hospital from May 16th, for the purpose of giving a short course of lectures in dentistry to surgeons passing through the course at the hospital, and to otherwise educate them in the simpler operations of dentistry. He will also perform all the dental operations required at the hospital and on board the *St. Vincent*, and in the interval between the two courses of instruction visit the *Boscawen* at Portland periodically, and if possible the Marine Division at Chatham and the Marine Depôt at Walmer.

NURSES AND RELIGION.

PROFESSOR VIRCHOW, in the Berlin Municipal Council and in the course of a debate on the new Municipal Hospitals, has been speaking in his most vigorous style against what he is pleased to call "the intrusion of religious arrogance" into hospital nursing work. "Everybody knows," he says, 'that creeds claim supremacy in the healing of the sick; but we are profoundly interested in keeping away this conflict from the sick bed, and in permitting the spirit of humanity alone to assert itself there. ..... The community establishes numerous hospitals, and thus has an opportunity of providing for the training of sick nurses without regard to creed." Such is the gist of Professor Virchów's characteristic deliverance on this question. We are bound to admit that the advocates of "creeds," as distinguished from the advocates of religion in the large, broad, human sense of that indispensable word, have fairly exposed themselves to this attack. They have often laid themselves open to the charge of using the hospital and the accident of sickness as means of proselytising. But whatever it may be in Germany, we cannot in England afford to divorce religion from hospitals. They are a field on which Jews and Christians, Protestants and Catholics coöperate, and even learn to respect each other's religions. Hospitals in this country so far are neither State institutions nor Municipal ones, but voluntary. And religious people have been their chief founders and supporters. The "spirit of humanity" has its chief expression and example for us in Him whose supreme test is in the words "I was sick, and ye visited me." If religion will keep on such lines it will not be easily expelled from our hospital service. If it does not, but worries the sick with narrow questions of sect and creed, it will be dislodged from its high position.

PUBLIC HEALTH AND VACCINATION IN FRANCE.

A PUBLIC HEALTH BILL for France is proposed by the Minister of the Interior, who includes in his office a sub-department of public hygiene, and in accordance with a very useful French custom the Bill is accompanied by an *exposé des motifs*, which sets out a detailed statement of the advantages of the Bill generally, and an explanation of the significance and value of each separate section. Lengthened quotations are contained in this *exposé*, embodying the views of such men as Fauvel, Rochard, Brouardel, Proust, and A. J. Martin; but it is impossible not to see in the document the handiwork of M. Henri Monod, the energetic and able head of the department of Public Health. M. Monod has made himself thoroughly conversant with the results of sanitary administration in other European countries, and he does not fail to point out to his countrymen the advantages they will secure if in certain respects they follow the lead of others. The document is especially complimentary to England and to the sanitary administration which is organised under the supervision of the Local Government Board, and the French nation is reminded that if they could succeed in securing a saving of life from the more preventable diseases such as has been obtained in this country since the passing of the Public Health Act (1875) they would gain no less than 130,000 lives annually. The Bill contains a compulsory clause which in its working is not unlike Section 299 of the English Public Health Act, although the initiative in providing works without compulsion does not appear to lie so completely with the inhabitants of the actual district to be benefited by them as is the case with us. Article No. 8 is instructive at a time when we in this country seem to be hesitating as to compulsion with regard to vaccination. The clause follows rather the Prussian than our existing English precedent. It enacts that primary vaccination shall be compulsory before the end of the first year of life, and that revaccination shall also be compulsory, a first time during the tenth, and a second time during the twenty-first year of life.

REJECTION OF THE STOKE NEWINGTON HOSPITAL SITE.

BY a majority of one, the motion to build another fever hospital for the purposes of the Metropolitan Asylums Board at Stoke Newington has been rejected. The objections to the site were, in the main, two in number. First, deterioration in the value of property—an evil that must be faced anywhere if a hospital is to be provided within reasonably easy reach of those whom it is to serve; secondly, the fact that the New River runs through an angle of the site. Small-pox was not in question, and we have thus far no definite evidence to the effect that the contagia of the other specific fevers would so travel aerially as to contaminate an adjacent flowing stream. On the other hand, it cannot positively be asserted that no such occurrence is possible, and hence, had the site been taken, it would have been proper to have culverted the river at this point. But, on the whole, the decision arrived at is perhaps the wisest.

THE ROYAL COLLEGE OF VETERINARY SURGEONS.

IT would appear that the members of the veterinary profession are no more agreed among themselves as to their position with regard to the Council of their Corporation than are those of our own profession, though they have less cause for complaint. It seems that some years ago the Royal College of Veterinary Surgeons applied for and obtained a new charter, giving it power to institute a Fellowship degree. This degree was conferred upon a certain number of the more distinguished of its Members who had been some years in practice, and on payment of a specified sum. These were Foundation Fellows. Afterwards the Fellowship was given only to those who had been at least five years in practice, and were certified by three Fellows to be fit and proper persons, after passing a written and oral examination and paying a larger examination fee than the Foundation Fellows had done. The inducement held out to Members to become candidates for the higher grade, was that Fellows alone were to be eligible to

Digitized by Google

act as members of Council and of the Examining Board. For ten or eleven years Members have become Fellows and paid their money with this inducement before them; but now another charter is applied for which is to deprive Fellows of the sole privilege of being members of Council, and this is resented by a number of the Fellows, who have appealed to the Privy Council against the deprivation, pointing out that they have spent time and money and suffered much inconvenience to obtain the proffered privilege. They also show that by having gentlemen as councillors who have been a certain number of years in practice, have a recognised social position, and have given proof of their zeal and capability, the public and the Government have a guarantee that the affairs of the profession are in good hands. How far the Privy Council is likely to accede to the desire for a new charter, or whether it will recognise the agreement between the College and the Fellows as binding and to be maintained, it is, of course, impossible to tell. But it appears that every Member who has been five years in practice can become a Fellow on the prescribed conditions, so that there is nothing prohibitive to becoming a Fellow. Another important matter is that every registered Member of the College can vote for members of Council, voting papers being sent to them for every election. This, it will be seen, is a very different case to that of Members of the Royal College of Surgeons.

THE SANITARY STATE OF SOUTHEND.

WE regret to have to recur to the subject of the sanitary state of Southend. But, in view of the past history of this town and of our former comments on it, we should take upon ourselves a serious responsibility if we did not at least warn holiday-makers to seek medical advice before deciding on the houses they intend to occupy. The most recent information which reaches us is as to sewage-flooded cellars in the town, and we need hardly say that houses that have thus suffered are not residences to be occupied even by the healthy, to say nothing of those who, after heavy work, seek for a brief space the rest and healthful influences of a seaside resort. We would at the same time call attention to the fact that the Local Board of Health have shown their determination to rid their town of its present unwholesome influences by calling in the services of Mr. Mansergh, C.E., and if they do all he recommends, they will at least have taken ample measures in so far as the public sewers are concerned.

APRIL WEATHER.

AMPLE proof has been afforded us during the past three weeks of the proverbial fickleness of April weather. Ten days before Easter we were in the apparently settled enjoyment of a season mild, sunny, and dry, the precarious foretaste of summer which commonly cheers for a brief space the later days of spring. Then follows the biting chill of winter winds, with rain and the very unusual addition of a snowfall worthy of December. The variations in temperature during the month have been correspondingly wide, falling repeatedly to near freezing point, and again on the same day reaching a level of 40°, 50°, or 60°, and even higher. It would have been extraordinary indeed if we could not trace the incidence of changes so frequent and so sudden as these by corresponding effects upon the health of those exposed to them. Such undesirable evidence is to be found in the recent prevalence of catarrhal ailments, though these have not been associated in the degree which might have been expected with inflammatory illnesses of a more serious character. In view of the present atmospheric depression, alike as to temperature and density, we may fitly recall the fact that the present season follows on a period of similar depression in the physical power of individuals, which reaches its close at the spring equinox. It is consequently no time for the remission of what may appear to some superfluous precautions in the matter of bodily warmth, and in particular of warm clothing. There are many persons who readily forget this fact in the temporary discomfort caused by wearing somewhat heavy clothing during a short and summer-like interval. This is natural, no doubt, in its way, for vegetable growth, in like manner, trusts the passing time and comes forth, to be afterwards nipped by a chill. Even in this case, however, man is in the greater error. In the case of the plant exposure is gradual; in that of man, too often immediate. With the former, too, each interval of mildness has to be snatched, as it were, for development; but man can wait for the luxury of physical comfort. In the interest of that greatest comfort, health, we would advise him to wait, until at all events the chilly nip, which always comes about the middle of May, is over, or even until the month itself is "out."

CLOSETS FOR THE WORKING CLASSES.

THE Midland Branch of the Association of Medical Officers of Health have unanimously condemned the midden-privy system and the pail-closet system for large towns. They maintain that water-carriage, by means of which excreta are rapidly removed from the neighbourhood of dwellings, is the only desirable method; and Dr. Bostock Hill, who brought the matter forward, urges that the Birmingham automatic slop water-closet has solved the difficulty. The report which was recently issued by the medical officer of the Local Government Board on this subject, taken together with the opinion of the health officers, will doubtless serve to stimulate action in this direction; but, on the other hand, it must be borne in mind that several requisites are essential to the proper working of this system, and that, unless these requisites are obtainable, the slop water-closet cannot be regarded as a proper one to supply to the working classes. Amongst these conditions are an ample water-supply actually laid on to the houses, means for storage of slop water, and means for its discharge automatically in bulk. Where these are not available, dry systems offer a better chance of freedom from nuisance, and such failure as has attached to this latter method has often been due to faulty construction of closets and neglect of the sanitary authorities to undertake their cleansing—evils that can easily be avoided.

ANTI-VACCINATIONISTS DEFEATED.

WITH what sounds very like the first warnings of a small-pox storm in the country it is gratifying to have to record the triumph of common sense in the form of a decided defeat of the anti-vaccination candidates in the recent guardians' elections at Guildford. They were not only beaten in all the parishes, but they were beaten by larger majorities than on the last occasion. Small-pox is the real schoolmaster to direct people to the vaccination stations. But the majority of English parishes should have sense enough to take the account of small-pox from history or from the experience of others, without waiting till it attacks themselves or those dearer to them than their own life.

SANITARY PROGRESS IN VICTORIA.

SINCE Dr. Astley Gresswell was appointed chief health officer to the colony of Victoria he has been most actively employed in learning the sanitary circumstances of the population, and he has at every opportunity sought to rouse the inhabitants to the realisation of the necessity of a higher standard of health, basing his advice very largely on the experience which he gained in this country, and which he knows so well how to adapt to the local circumstances prevailing in his present sphere

Digitized by Google

of labour. Some of the reports which he issues on local outbreaks of disease remind us very much of our practice at home; one set being prepared by local inquirers and prefaced by him, in order to bring out those lessons which are of general application; others being exclusively from his own pen, and these deal ably, but at times trenchantly, with the local sanitary shortcomings. Amongst the most recent documents issued is one as to the need of providing means of isolation for persons affected with communicable diseases in Melbourne, and here also Dr. Gresswell sets out many of the arguments which in this country have aided in promoting the extension of a system by which isolation hospitals are provided by sanitary authorities.

FOREIGN UNIVERSITY INTELLIGENCE.

Berne.—Dr. Tavel has been appointed to the chair of Bacteriology.

Clausenburg.—Dr. Ladislaus Udránzky of Buda-Pesth has been offered the post of Extraordinary Professor of Physiology, vacant by the transfer of Professor Klug to Buda-Pesth.

Innsbruck.—Dr. Philipp Biedert, of the Bürge Hospital of Hagenau in Alsace, has been offered the Professorship of Children's Diseases.

Prague.—Bohemian University: Dr. Carl Chodounsky, *privat-docent* in Pharmacology &c., has been granted the position of Extraordinary Professor. German University: Dr. Rudolf Fischl has been recognised as *privat-docent* in Children's Diseases.

Vienna.—Dr. Paul Dittrich has been officially recognised as *privat-docent* in Forensic Medicine.

Würzburg.—Dr. Gustavus Klein has been recognised as *privat-docent* in Midwifery and Gynæcology.

THE academic world in Italy is congenially employed in celebrating the fifth centenary of the University of Ferrara, a decaying seat of learning, which the Town Council recently memorialised Government to suppress. There are too many universities in Italy, and graduation at them is so easy, particularly in the faculty of law, that the country is more than overstocked with "avvocati." To halve their number and to double their efficiency is what many of her reformers are urging.

THE Medical Society of London will give a conversazione in their rooms, 11, Chandos-street, Cavendish-square, on Monday, May 2nd. The oration on "Sex in Education" will be delivered by Sir James Crichton Browne, M.D., F.R.S., at 8.30 P.M. There will be a reception by the president at 9.15, and smoking will be permitted at 10 o'clock. The string band of the Royal Horse Guards will attend.

A Reuter's telegram from Genoa states that the steamer *Duchessa di Genoa*, with 872 passengers from Brazil, arrived there with yellow fever on board. Five deaths had occurred during the voyage. The vessel is lying in quarantine off the coast of Sardinia.

THE death of Elijah Whitney, M.D., the oldest practising physician of New York, has occurred at the age of ninety-four. He was a personal friend of Webster, Clay Calhoun, Wendell Phillips, and all the men prominent in Government circles before the War of Secession.

SIR JOSEPH FAYRER has been elected a corresponding member in the Class of Mathematical, Physical, and Natural Sciences of the Royal Academy of Science of Lisbon.

MR. REES MORGAN, L.R.C.P.Edin., L.F.P.S.Glas., has been appointed deputy coroner for the Eastern Division of Carmarthenshire.

PROFESSOR STEWART'S LECTURES
AT THE
ROYAL COLLEGE OF SURGEONS OF ENGLAND.

PROFESSOR STEWART, Conservator of the museum of the Royal College of Surgeons, delivered last month in the theatre of that institution a series of six lectures on "The Physiological Series of Comparative Anatomy in the College Museum." He said no collection in the museum was more richly supplied with specimens than the physiological series, and it was probably the portion which was dearest to the heart of Hunter, since he of all men felt most clearly the importance of studying the various forms of living things, believing so thoroughly that they threw light one upon the other, and that some knowledge of them was at all events desirable for the medical man, not only as a form of culture but as a means of broadening his mind and of giving him a view of the phenomena of life which the study of man alone could in no way bring about. The rearrangement of this series had been a task ever present before Professor Stewart as one of the most immediate necessities of the future. In order, as it were, to lay the foundation for this work he had drawn up a scheme, provisional in its nature, for his guidance in the contemplated work. He proposed to break up the physiological series into a number of groups indicated by letters of the alphabet and each to be independently numbered. Thus, regarding first those structures concerned in the preservation of the individual or to its advantage, in Group A, taken purely as a matter of convenience, which he had been obliged to consider, rather than any rigid or absolute law, he included the endoskeleton, by which is meant all those more or less deeply seated structures concerned in giving support, strength, rigidity, and protection to more deeply seated parts; and in some cases furnishing the levers and fulcra for the movements of parts of the body and giving attachment to the muscles, its physical properties being independent of life. In the next group, B, he intended to arrange all flexible bonds of union and support, either as connecting soft parts or rigid structures; C would contain the contractile and muscular systems; D, organs for locomotion, floating, boring, and fixation; E, the nervous system; F, organs of special sense; G, integumentary system and exoskeleton; H, luminous and electric organs. Regarding, in the second place, those organs concerned in nutrition, Group I would include reserve stores of food and calorific matter; K, the organs of direct absorption; L, the organs of digestion; M, nutrient fluids and organs that prepare them, including the ductless glands of unknown function, blood, lymph, and blood and lymph elaborating organs; N would deal with the circulatory system and body cavity. Under the third great head of blood-purifying and sound-producing organs would come—O, the respiratory system; P, sound-producing organs (including the larynx and syrinx; Q, urinary organs (including kidneys and bladder); R, specialisation and division of labour amongst "persons" or "individuals." In the fourth great head, the structures concerned in the preservation of the race would be arranged thus: S would include the reproductive system; T, structures for the protection of the young (including eggs, egg capsules, nests, &c.); U, structures concerned in the nourishment of the young, including mammary glands and placentæ; V would possess illustrations of the various steps in the development of different creatures, and would be supplemented by models. Then would follow certain series not falling under any of the previously mentioned heads, but of which it would be convenient and necessary to have examples. Under W would be brought together all the specimens which serve to illustrate secondary sexual characters—that is, those characters which distinguish the sexes from one another, but which are not directly or indirectly concerned in reproduction. This would include also sexual dimorphism and polymorphism. Under X would be grouped illustrations of normal variations of species; and Y would show the association of different species with or without modifications of structure, those curious associations which may be either for the advantage of one without injury to the other (commensalism), for the advantage of all the associated forms (symbiosis), or for the advantage of one, more or less at the expense of the other (parasitism).

The six lectures were intended to illustrate as far as

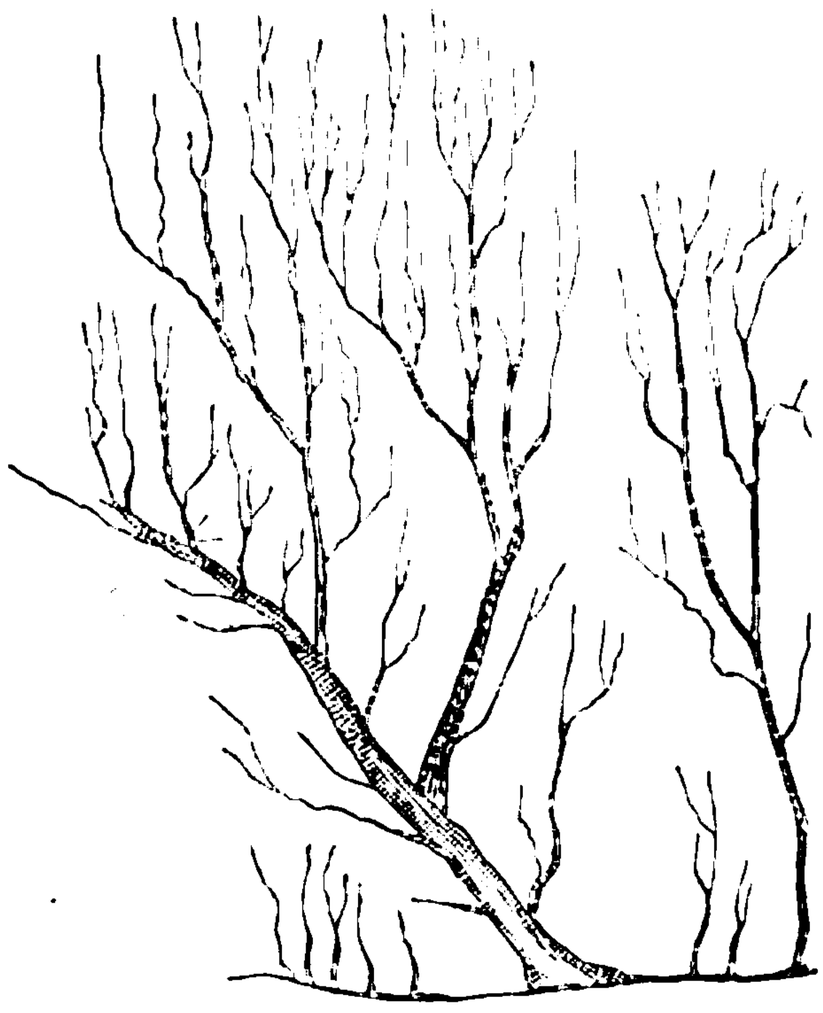
Digitized by Google

possible the idea underlying the proposed grouping of the series as recorded above; and it is with a view of showing this—as well as of presenting to our readers the intensely interesting nature of these lectures of Professor Stewart, illustrated throughout as they are with such artistic facility and beautiful specimens, and abounding with information regarding living organisms which cannot fail to stimulate the hearers to seek further knowledge of such subjects—that we give the following brief outline of the course. Beginning with Group A—which includes all structures that function, as endoskeleton, whether derived from ectoderm, mesoderm, or endoderm, or the equivalent embryonic layers,—and first taking up the lowest forms and the simplest types, the lecturer showed instances in plant life of the existence of an endoskeleton. The fibro-vascular bundles of plants, familiar to many as giving the stringiness to celery and other plants, were not only merely conducting tissue, but acted also in part as an endoskeleton. These bundles were, however, so much concerned in conduction that they would fall under another group. Certain red and green algæ might have a hardness and rigidity due to lime salts which clearly was not endoskeletal in nature or function. But examples of a true endoskeleton could be found among the algæ as bundles of prosenchymatous cells with some extra thickness of their walls. In delesseria sanguinea this condition is found as the tissue traversing the axis of the thallus and lateral branches diverging from it. Amongst the fucaceæ it is present, and attains its maximum development in various species of turbinaria. Of these the structure was demonstrated on the blackboard. In ferns and club mosses deep-seated bands of this tissue of extreme hardness contributed towards the strengthening of the stem. In palms similar structures were found associated with each of the fibro-vascular bundles, and the duramen or heart wood of the ordinary exogen might also be considered as endoskeletal; though also in part it is the place where sundry waste products in the way of resins and colouring matters may be deposited. In the remarkable African plant, the Wellwitschia mirabilis, an extreme development of large thick-walled spicular cells, giving it strength and stiffness, was noted. He then alluded to the modified crystals of lime (raphides) salts found in the squill, hyacynth or tulip, serving to defend them from slugs or insects which subsist on vegetable tissue. These plants often had an exceedingly acrid taste, not due, as has been supposed, to their juice, but to the mechanical irritation of the tongue caused by these crystals (raphides). Proceeding to the animal kingdom examples were sketched from the heliozoa and the radiolaria. In the latter the endoskeleton was present as a perforated organic capsule separating the inner and outer portions of the protoplasm. In addition to this there might be spicule-like bodies of acanthine or siliceous material or a complex network of solid siliceous bars.

In the metazoa an endoskeleton might be present as isolated spicules of a calcareous nature in the calcareous sponges, and of a siliceous nature, and exceedingly varied in form in the siliceous sponges. The various forms were admirably sketched on the blackboard. In the horny sponges it consisted of a network of horny fibres closely allied to elastin, with which foreign bodies were sometimes incorporated. Coming to the hydrozoa, a structureless supporting lamella between the two layers of the body wall formed the endoskeleton, a layer which became thickened in the smaller medusæ; and in the more complex forms acquired a character resembling the connective tissue of the umbilical cord, from the migration of cells into it and the formation in the matrix of a fibrillary structure. It was interesting in these forms to notice that the endoderm might enter into the formation of the endoskeleton, the solid prolongations of this layer into the tentacles often acquiring a character resembling the notochord in the chordata. This gradual development was illustrated in detail by sketches of the structure of various creatures representing its stages. In the echinodermata the lecturer said that it was convenient to consider only such specially deep-seated parts of the skeleton—as, for instance, the jaw apparatus and auriculæ of the echinoidea and the circumoral plates of holothurians, which gave attachment to the great longitudinal muscles of the body and the axial plates in the arms of ophiurids—as examples of this structure. In the higher arthropoda, as the lobster, involutions of the integument which formed a calcified cuticle formed the endophragmal system and performed the function of an endoskeleton. Besides this, another form of endoskeleton derived from the mesoderm was present in some. In apus, for example, there lay a deep-seated plate, with outlying processes giving attachment to the muscles situated between the nervous system and the alimentary canal, and possessed of the structure of fibro-cartilage, but having the chemical composition of chiten. This peculiar portion was known as the endosternite. This endosternite attained large dimensions and much importance in the limulus, in which creature it had essentially the same structure. In the spiders it acquired very great complexity of form, but maintained essentially the same minute structure. In the scorpion, a portion of it formed a broad plate, separating the abdominal region from the cephalo-thoracic. In insects, amongst the lepidoptera (butterflies and moths) a curious rod-like body is described by many naturalists lying in the abdomen immediately above the central nerve cords. Further investigation of the structure was much required. In the great group, mollusca, the development of the shell removed the necessity for any large development of endoskeleton, but certain cartilaginous plates existed, forming, as it were, a bed on which to rest the rasp-like tongue, and to which the muscles of that organ were attached. In cuttlefish, active free swimming forms, a large development of a cartilaginous endoskeleton existed, most of the cartilages showing in the matrix, cells, freely communicating with one another by processes of their substance. One of the cartilages of the globe of the eye (equatorial) differed from the others in the cells being without such processes, but each was surrounded by a small amount of firm intercellular substance. These cartilages were drawn, and a beautiful preparation was used to illustrate the anatomical features. In the chordata forms, which had as a common feature the detachment of a rod-like group of cells from the alimentary canal in order to form the cartilage-like notochord, the structure was found as an axial support of the tail in urochorda. Of this an account of the general structure of the appendicularia was given as an example.

In the hemichorda the anatomy of a remarkable worm-like form (balanoglossus) was sketched, the notochord being shown to be present as a rod extending from the first part of the alimentary canal into the proboscis. In amphioxus the notochord was shown as a rod stretching the whole length of the body. Besides this, a series of cartilage-like structures were present to support the dorsal crest, a delicate rod-like bit on either side of the mouth, with extensions into the oral fringe, and a bar-like thickening extending along either side of the body walls. In the craniate forms of true fish, in lampreys and their allies, a highly developed cartilaginous skeleton could be found. In the elasmobranchs (sharks &c.) the endoskeleton was mainly composed of cartilage, but with minute plates of calcified cartilage usually present on its surface. Calcification of cartilage, such as occurs in the larynx of old people, occurred in this group as a normal feature. The lecturer recapitulated the views held on this subject. Possibly the group of cells in each plate was descended from one parent-cell, having something in its character which prevented the calcification extending into neighbouring groups. Each plate remained distinct from its neighbour, and each plate showed a radiating arrangement of the cartilage cells contained within it. In the bony fish and ganoids, where the structure was hardened by lime salts, great and interesting differences were found in the minute structure of the tissue. In the common garfish or green-bone the bones were remarkable for the emerald green colour of the matrix, and the bones of the head at all events showed a complete absence of lacunæ and their canaliculi, the tissue having a character resembling dentine due to branching tubes extending inwards from the surface, as is shown in Fig. 1.

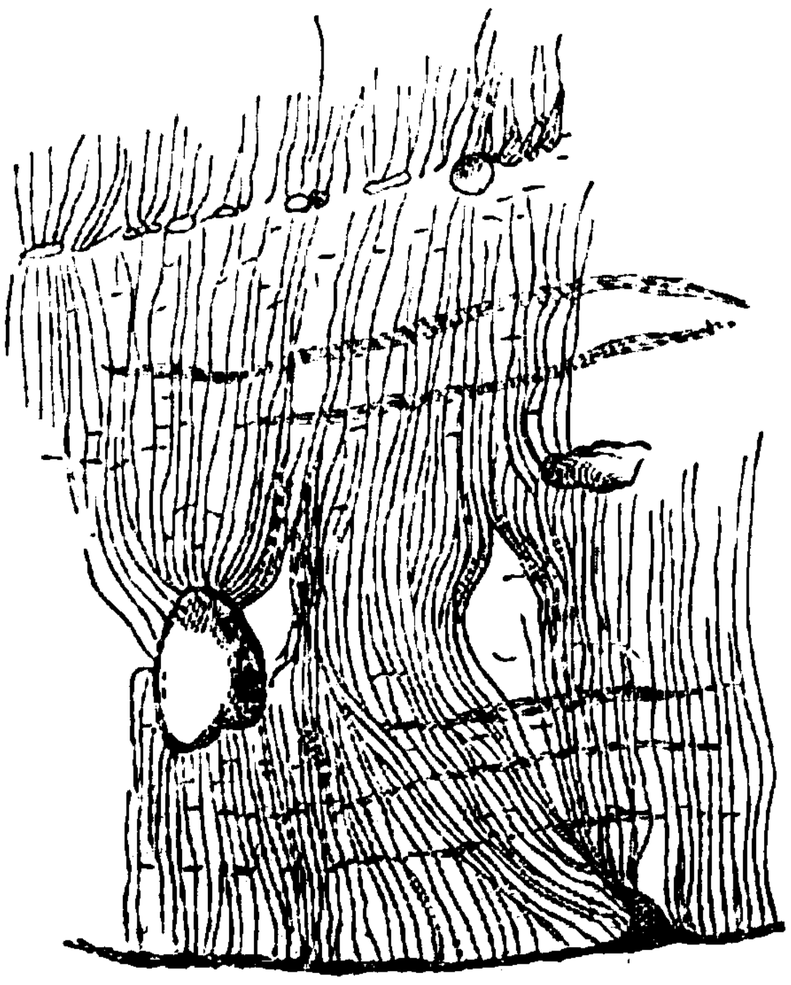
In the bones of the seahorse similar tubules were to be found radiating from all the vessel containing channels. As these were much finer than in the former case the resemblance to dentine became exceedingly close. Some idea of its structure will be obtained from Fig. 2.



The intensely hard bone of the swordfish, the microscopical structure of which is given in Fig. 3, consists of a solid bony matrix surrounding each vascular channel. Evidence of its intense hardness and strength, and of the force with which the fish can propel itself through the water, was given by the exhibition of a specimen of a preparation of the hull of a ship, which the fish probably had mistaken for a whale, of which the copper sheeting, teak, and oak, amounting in thickness to thirteen inches, had

Digitized by Google

been completely penetrated by one thrust of its bony weapon.



In amphibia the large and varying proportion the cartilage bore to bone constituting the skeleton was indicated, and the fact pointed out that the large bones of many extinct reptiles were rendered light by their medullary cavities being occupied by air-filled chambers continuous with the great air sacs, which communicated with the lungs, a feature similar to that which is well known in most birds,

FIG. 1.

but which has, however, no relation to flight, but served simply to lighten the skeleton for any purpose. The greater number of Haversian canals, the more tortuous canaliculi connected with the lacunæ, was pointed out as being a common characteristic of the bones of birds, and the pneumatic feature either in them or in reptiles was always associated with circumferential lamellæ, in them always bounding the medullary cavity instead of the outer surface of the bone. The typical mammalian structure was of

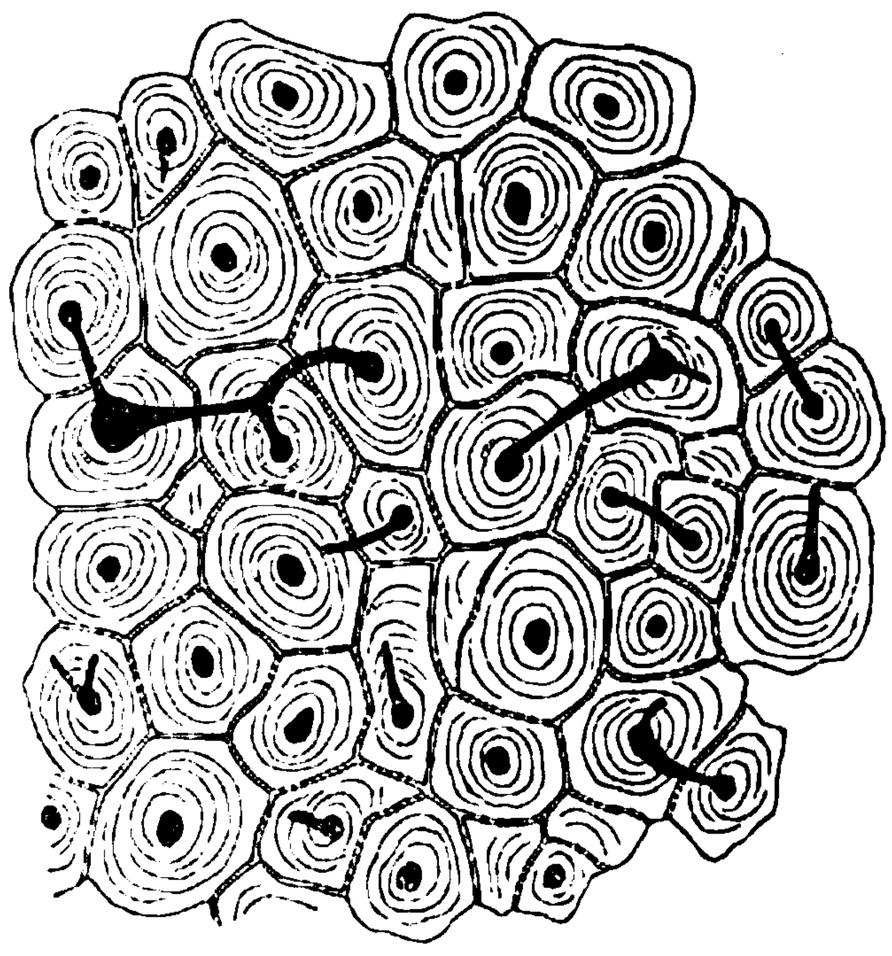


FIG. 2.

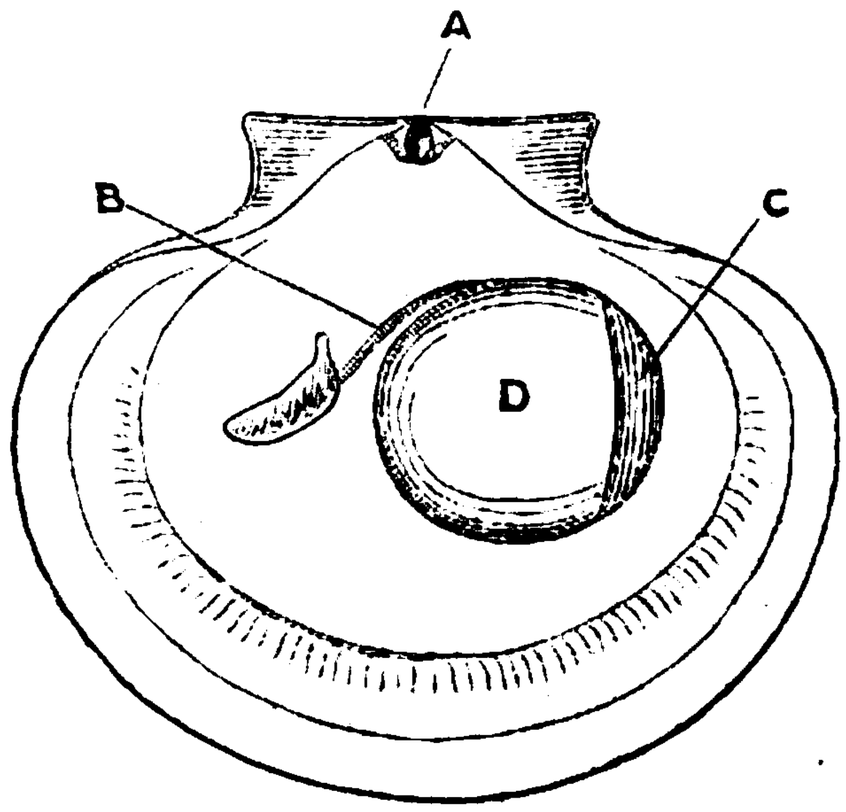
course presented by human bone, of which it was not necessary to speak with detail; but a peculiar feature was pointed out in the ornithorhynchus—namely, that although lacunæ with their canaliculi were present, yet many of the Haversian canals showed long tubules directly radiating into the surrounding matrix, resembling one of the dentine-



Group A, the lecturer next went on to illustrate the mode of arranging Group B by giving a general account of the familiar structure of areolar tissue formed by the web-like interlacing of wavy bundles of white fibrous tissue and fibres of yellow elastic. It loosely connects and supports parts allowing movement in any direction with spontaneous return to position of rest. The illustrations were drawn on the blackboard. Yellow elastic tissue was next exemplified by the specially developed layers of the abdominal walls of

FIG. 3.

ruminants. Then the bonds of union connecting hard parts were taken up. The crustacea furnished examples of these, certain portions of the cuticle remaining flexible and free from calcification, and serving to unite the stiff calcified regions. A drawing was made to illustrate these two parts. Examples of elastic union were taken from the internal or external elastic ligaments of the bivalves. The common pecten furnished an illustration (see Fig. 4) of an elastic spring compressed when the valves were closed, and by which they were forced apart when the muscles ceased to contract. The elastic ligament of the cockle, on the other

FIG. 4.

A, Elastic ligament. B, Retractor of foot. C, Non-striated, for closing valve. D, For swimming—striated.

hand, being placed outside, was stretched when the valves were closed, and served to pull them apart by recoil when the muscles were relaxed. Then the great class of ligaments belonging to the endoskeleton and which were extensile and elastic, was illustrated by the ligamentum nuchæ, say, of the giraffe and the ligamentum subflava. Examples of non-extensile ligaments were taken from the ligaments of the vertebræ, the structure of which was given, and [illegible]

muscular systems, a general account of the movements of protoplasm, with the phenomena of movement in the sensitive plant, was recounted. The arrangement of muscular tissue in various groups of animals, beginning at the lowest, was described and drawn. After giving the structure of the two great groups of muscular tissue, it was pointed out that to a great extent it might be considered true that the more complex striped tissue was associated with quickness of contraction, it being present in the quickly contracting muscle of the subumbrella of hydrozoa, in the tentacles of hormiphora, in all the muscles of the arthropoda with the single exception of peripatus, which had unstriped muscle like a worm. In the branchopods a remarkable exception to the usual character was found to the usual unstriped character of the muscular tissue, in that the posterior occlusor muscle is beautifully striped. In bivalves the greater portion of the great adductor muscle in pecten, which is used for swimming, is striped; while the small posterior part used in maintaining the closed condition of the valves is unstriped. Then, in the sea-squirts the heart muscles are striped, but the mantle of the fixed forms is unstriped; but where the mantle muscles are subservient to locomotion they are striped, as in salpa. The lecturer remarked in passing that the presence of hæmoglobin in the buccal muscles of many gastropods and in the sphincter at the mouth of the sea anemones might possibly in these cases account for their greater energy of action.

LIFE ASSURANCE AND THE MEDICAL PROFESSION.

THE interest manifested by many of our readers on the subject of Life Assurance has led us to examine with some care the various reports and statements of account which have reached us during the present year, and to prepare for the information of those among them who are concerned with the subject the following notes upon what appear to be their most salient points:—

The *Alliance* is a comparatively young but vigorously administered office, which annually receives a large accession of new members. Its report for the past year exhibits no striking feature, but records a steady advance along the accustomed lines of movement. The *Atlas*, as a very old established office, produces a report in which the most salient feature is the great age of the deceasing members, the amount shown as disbursed in claims having been paid to the extent of more than 60 per cent. in respect of deaths occurring among persons upwards of seventy years of age. The *Equitable of the United States* is a younger office, and, as its name indicates, of American origin. But it brings out results of the most astonishing magnitude, and with an income exceeding £8,000,000 a year it fitly supports the reputation of America for doing things upon a large scale. The *Marine and General Mutual Life Assurance Society* is not as old as the *Atlas*, nor does it transact as large a business as the *Equitable of the United States*, but its premium income has been well sustained during the past year, and, what is much more important, the pressure of working expenses upon the revenue has been appreciably lightened. An excessive mortality, due probably in greater or less degree to the prevalence of influenza during the period under review, has marred the financial result of the year's operations, though without making the mortality experience of the company abnormal if a period of three years past is included in the review. The *Railway Passengers' Assurance Company* is at once the largest and best known of the companies which transact accident insurance business. Its report shows that compensation of the kind provided by its policies has during the year been paid to an amount approaching £150,000, a figure which indicates not only widespread connexion, but also an incalculable amount of relief of the pecuniary distress which every-day misadventures cause. *The Economic Life Assurance Society* has just undergone a process of remodelling by the substitution of new rules and regulations for the deed of settlement under which its business has heretofore been carried on. The directors report that they have availed themselves of these new regulations to revise and improve the conditions upon which the Society's policies are granted. *The English and Scottish Law* makes the growth of its business during the past year the great feature of its report. The accounts disclose a very heavy rate of working expense, which does more to explain than to justify the popularity of which the directors make their boast. *The London and Lancashire* is a comparatively young office, but it obtains a very considerable proportion of new business. Like most other young assurance companies, it obtains its results at a comparatively heavy working cost; but the fault is one which it tends to outgrow. The *Mutual Life Assurance Society* exhibits a record which, upon the crucial question of economy of resources, is entitled to very high rank. The present annual report presents the result of consistent attention to this matter in the shape of a very handsome surplus for distribution among the policy holders as the outcome of a recent valuation. The report of the *Law Union Fire and Life Insurance Company* records the result of an amalgamation recently effected with the *Crown* office. The accession has naturally produced a large augmentation of revenues; but in the life department it has been made the occasion of providing for depreciation of securities and extension expenses by the sinking of a sum of £20,000, an item which quite spoils the financial result of the year's operations. The *Gresham Life Assurance Society* transacts so large a proportion of its very extensive business abroad that it is difficult to find a standard of working cost by which to test the merit of its administration in respect of economy. The valuation test yields a very satisfactory result in the shape of a divisible surplus of upwards of £80,000 as the outcome of three years' working and the result of a 3½ per cent. valuation. An important change has just been effected in the constitution of the Society, by which its policy holders acquire a larger interest than heretofore in the surplus from time to time divided. The *New York Life Insurance Company* has undergone during the past year a very searching investigation, from which it has emerged by no means scatheless. The report of the Insurance Commissioner of New York has, however, established the all-important point of the Company's solvency, and in their present report the directors refer to changes of *personnel* which they say will remove whatever doubt may have been felt as to the future administration of the Company's affairs. The *London Life Association*, an office which has long and deservedly enjoyed the very highest reputation among "those who know" for economy and the efficiency which results from economy, has just issued a new premium table, under which half-premiums only are at first chargeable, the bonus being expected to reduce the full premium to something like the same figure as the original half-premium by the time that the half-premium term has worked out. The scheme is intended to compete with the "assessment" schemes which have attained to a great, though wholly unmerited, popularity within the past few years; and being undoubtedly sound, whether regarded from this point of view or in the broader aspect of a new attempt to adjust the means of a life assurance scheme with some precision to its ends, it is deserving of great praise.

(To be continued.)

THE CONTAGIOUS DISEASES ACTS.

A LEADING article in the *Times of India*, published at Bombay on Feb. 26th last, draws attention to the evil caused by the abrogation of the Contagious Diseases Acts. Last year the editor of this same paper felt it a duty, distasteful though the subject must be, to draw public attention to the statistical revelations of the spread of the disease throughout the European army in India as contained in the last annual report of the Sanitary Commissioner with the Indian Government. The writer notices with gratification "that the outcry against this fatal mandate of repeal is becoming at home more powerful year by year as the evidence of the ruin wrought among men and women alike in garrison and seaport towns accumulates with sickening intensity." After glancing at the state of matters in the army and navy at home before the passing of the Act of 1864 and subsequent Acts, at the results of the Acts in effecting a reduction of disease wherever they were enforced, and the results of

Digitized by Google

their repeal, the writer passes from the men to the women in words which may well be reproduced :—

The social evil is one of the saddest blots on the progress of civilisation, nor is it the shrieking sisterhood alone who are left to bewail it. If shrieks could abolish it all humanity would join in the hue and cry. Unfortunately, it is a stern fact, which the best endeavours of the wisest and kindest of mankind can only do something to modify. These wild agitators forget that the policy they advocate is as heartless as it is blind and inconsequent, for it strikes at the very people whom they most design to save. Let the men, if it must be so, suffer the consequences of their folly; but is that any reason that the unfortunate women, more sinned against than sinning, should be abandoned to the horrible consequences of the life they lead? It should be proclaimed with emphasis that the other sex reap at least as large benefits, and it is humane to see them protected from the consequences of their misfortune, their ignorance, or their guilt. We do not envy the spirit of cruel inhumanity that, parading under the sacred mantle of morality, abandons the most pitiable of their sex to the fellest of diseases to protect themselves from its ravages just as they like and however they can. That these Acts should be attacked in the name of womanhood is proof of one of the most signal outbreaks of demented fanaticism that was ever provoked by a hysterical cry. It is precisely womanhood in its most helpless and appealing conditions of abandonment, reckless of the consequences from the very nature of its environment, it is womanhood that ought to be rescued and cared for, and protected from the physical disorders of its own despair. The Acts had this consequence directly, but their indirect assistance in reclaiming poor women to a better life was also immense, though not capable always of demonstration by statistics. It is impossible that the higher influences for good under which they were brought in hospital, by the kindly visits of clergymen and others, should not inspire, if not absolute conversion, at any rate wholesome leanings that are not without appreciable fruit. The wickedness of allowing such diseases to run riot through the army, taking into account the taint it impresses on an innocent posterity, has been harped upon sufficiently to open the eyes of the blind. Altogether, from whatever side these Acts are regarded, they are seen to be directed only to the operation of a truly benevolent work, and nobody with a fair mind and with a capacity for weighing the simple issues of a painful problem will for a moment charge the supporters of the Acts with the oblique purpose of making immorality safe.

It is hopeless to expect anything to be done, either by inquiry or legislation, during the existing Parliamentary session so far as the Government is concerned. But much might be done on the part of local authorities in reducing at least some of the worst phases of the "social evil" by providing hospitals for those who are diseased, by prosecuting those wretches, both male and female, who live on the wages of girls' and women's shame, and by increasing the provisions of "homes" and "refuges" in reclaiming those who are still reclaimable. We trust that the subject will be considered worthy of notice by some of the leading daily papers. We have done our part through evil and good report. Let the lay press do theirs.

FRENCH WORKMEN'S SANITARY CONGRESS.

DR. DUJARDIN-BEAUMETZ ON FOOD.

ON the 9th inst. the first of the preparatory lectures for the forthcoming French Workmen's Sanitary Congress was delivered by Dr. Dujardin-Beaumetz. There was a very large and attentive audience, almost all the trades of Paris were represented, and the workmen throughout manifested the greatest attention. The lecturer was introduced by M. Lavy, the Deputy for Montmartre, who represents the Possibilist labour party in the French Parliament. M. Lavy explained the reason why these lectures were delivered. The programme of their party had been affirmed with sufficient emphasis, and it was now time to turn from theory to practice. The object of the forthcoming Congress would be the study of the means of saving life. Workmen were now going to ask men of science what were the results of their investigations. Men of science were to tell the men of the workshop what they had learnt. It was with faith and with gratitude that the workmen constituted themselves the pupils of the learned professors who were about to address them. Their dreams of human equality did not prevent their recognising and paying homage to intellectual superiority. But they thought that those who had received much from society owed much to society. M. Lavy was glad to record that the professors who held the most eminent position in the domain of sanitary science had certainly placed their scientific [illegible] ing men. They would see that labour conferred a mark of dignity, whatever might be the nature of the work or the class by which it was performed. Nor would the advantage be exclusively on the side of the workmen present. The workmen would learn much; but when, in their turn, the workmen came and contrasted what was the actual condition of their lives with what the professors of sanitary science demonstrated as necessary for healthy existence, then perhaps the latter might learn something which had previously escaped their observation. After a few graceful and grateful compliments addressed to Dr. Dujardin-Beaumetz, M. Lavy invited the lecturer to deliver his address.

Dr. Dujardin-Beaumetz succeeded, with admirable tact, in explaining the technicalities of nutrition in such a manner as to be intelligible even to the simplest members of the audience. He first explained that nutrition depended on a sufficient supply of three chemical groups of substances. For a man at absolute rest 129 grammes of nitrogenous substances, 410 grammes of carbo-hydrates, and 35 grammes of fats were required. If the food-supply of Paris were examined, it would be found that it consisted of 120 grammes of nitrogenous substances, 330 of carbo-hydrates, and 70 of fats per head, which was not far from the theoretical amount considered necessary. This conclusion is, we presume, due to the including of children, infants, &c., in the number of the population, because the lecturer also explained that the French workman, when engaged in hard physical labour, required 190 grammes of nitrogenous matter, 600 grammes of carbo-hydrates, and 90 grammes of fats. The lecturer explained how much more heat was expanded when working, and greatly amused the audience by insisting that the human body was a very bad machine, inasmuch as it consumed nearly all its heat for its own maintenance, and barely spared more than one-fifth of its heat for the purposes of work. After describing the process of starvation and the evils of over-eating, he declared he did not believe in vegetarianism, excepting in hot climates. Wherever in cold or temperate climates meat was given, more work was produced. In spite of the doctrine so widely propagated that people could not be virtuous on beefsteaks, he thought that much of the success and energy of the British race was due to the fact that they were the most carnivorous people in Europe. With regard to alcohol, Dr. Dujardin-Beaumetz did not consider that it supplied heat. It was not an article of food, but it did act on the nervous system. It was a useful stimulant, but also a dangerous stimulant, for it produces inflammation and irritation wherever it passes. Finally, he was glad to note the growing preference given to coffee and tea, which stimulated the action of the heart and were far less injurious. The lecturer, having explained the nutritive qualities of various common articles of diet and how they could best be combined, insisted that it was not only necessary to have the required food, but it must also be digested. This latter problem must be solved by the housewife. Dr. Dujardin-Beaumetz was especially applauded when he showed that practical experiments demonstrated that more work was done in less time when better and more food was given. This had been proved more particularly when dealing with the mining populations. In conclusion, the learned professor thanked the Labour party for the initiative they had taken in organising their Sanitary Congress, and was sanguine that good results would ensue.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In thirty-three of the largest English towns 5572 births and 4080 deaths were registered during the week ending April 16th. The annual rate of mortality in these towns, which had been 22·2 and 23·3 per 1000 in the preceding two weeks, declined again last week to 20·9. In London the rate was 19·4 per 1000, while it averaged 21·3 in the thirty-two provincial towns. The lowest rates in these towns were 13·2 in Burnley, 14·6 in [illegible], 15·2 in Croydon, and 15·1 in Wolverhampton; the highest rates were 25·4 in Halifax, 25·9 in [illegible], and 26·2 in Liverpool. [illegible]

177 resulted from measles, 173 from whooping-cough, 50 from diphtheria, 43 from diarrhœa, 32 from scarlet fever, 19 from "fever" (principally enteric), and 1 from small-pox. The lowest death-rates from these diseases were recorded in Brighton, Portsmouth, Plymouth, and Halifax, while they caused the highest rates in Huddersfield, Sunderland, Swansea, and Sheffield. The greatest mortality from measles occurred in Leicester, London, Birmingham, Sheffield, Liverpool, and Huddersfield; from scarlet fever in Cardiff; from whooping-cough in Salford, Sheffield, Manchester, Bolton, Sunderland, and Swansea; and from diarrhœa in Birkenhead. The mortality from "fever" showed no marked excess in any of the thirty-three large towns. The 50 deaths from diphtheria included 32 in London, 3 in Salford, 3 in Newcastle-upon-Tyne, and 2 each in Portsmouth, Manchester, and Sheffield. A fatal case of small-pox was registered in Cardiff, but not one in any other of the thirty-three towns; 45 cases of this disease were under treatment in the Metropolitan Asylum Hospitals, and 11 in the Highgate Small-pox Hospital on Saturday last. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 1296, against 1227 and 1289 on the preceding two Saturdays; 146 new cases were admitted during the week, against 139 and 166 in the previous two weeks. The deaths referred to diseases of the respiratory organs in London, which had declined in the preceding four weeks from 523 to 403, further fell last week to 348, and were 75 below the corrected average. The causes of 71, or 1·7 per cent., of the deaths in the thirty-three towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Bristol, Sunderland, Newcastle-upon-Tyne, and in eleven other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Salford, Blackburn, and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 21·2 and 24·1 per 1000 in the preceding two weeks, declined again to 22·5 during the week ending April 16th, but was 1·6 per 1000 above the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 15·3 in Paisley and 15·6 in Leith to 25·5 in Glasgow and 27·5 in Perth. The 625 deaths in these towns included 24 which were referred to whooping-cough, 18 to measles, 10 to diphtheria, 9 to diarrhœa, 8 to "fever," 4 to scarlet fever, and not one to small-pox. In all, 73 deaths resulted from these principal zymotic diseases, against 65 and 66 in the preceding two weeks. These 73 deaths were equal to an annual rate of 2·7 per 1000, which slightly exceeded the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of whooping-cough, which had been 24 and 30 in the preceding two weeks, declined again to 24 last week, of which 17 occurred in Glasgow. The deaths referred to measles, which had been 15 and 14 in the previous two weeks, rose to 18 last week, and included 17 in Glasgow. The 10 fatal cases of diphtheria considerably exceeded those recorded in any recent week; 5 occurred in Glasgow and 3 in Dundee. The deaths referred to different forms of "fever," which had been 8 and 5 in the preceding two weeks, rose again to 8 last week, and included 5 in Glasgow. The 4 fatal cases of scarlet fever corresponded with the number in the previous week. The deaths referred to diseases of the respiratory organs in these towns, which had been 158 and 160 in the preceding two weeks, declined last week to 130, and were 12 below the number in the corresponding week of last year. The causes of 62, or nearly 10 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had declined in the preceding three weeks from 40·1 to 33·0 per 1000, further fell to 30·6 during the week ending April 16th. During the thirteen weeks of last quarter the death-rate in the city averaged 38·4 per 1000, the rate for the same period being 28·2 in London and 19·8 in Edinburgh. The 205 deaths in Dublin during the week under notice showed a decline of 16 from the number in the preceding week, and included 14 which were referred to measles, 6 to "fever," 5 to whooping-cough, 2 to diphtheria, 2 to diarrhœa, and not one either to small-pox or scarlet fever. In all, 29 deaths resulted from these principal zymotic diseases, equal to an annual rate of 4·3 per 1000, the zymotic death-rate during the same period being 3·0 in London and 1·2 in Edinburgh. The fatal cases of measles, which had been 24 and 23 in the preceding two weeks, further declined to 14 last week. The deaths referred to different forms of "fever," which had been 1 in each of the previous three weeks, rose to 6 last week, with one exception a higher number than in any week of this year. The 5 fatal cases of whooping-cough exceeded by 2 the number in the preceding week; and the 2 deaths referred to diphtheria were the first recorded in the city since the middle of January last. The 205 deaths in Dublin last week included 25 of infants under one year of age, and 52 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons showed a decline from the numbers in the preceding week. Seven inquest cases and 7 deaths from violence were registered; and 54, or more than a fourth, of the deaths occurred in public institutions. The causes of 21, or 10 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

Surgeon-Captain A. P. Blenkinsop is under orders for India.—Surgeon-Captain F. P. Nichols has been posted to the Secunderabad District, Madras command.—Surgeon-Captain W. Hallaran has been appointed to Bangalore, and Surgeon-Captain F. W. C. Jones to Mhow District, Bombay command.—Surgeon-Captain J. J. C. Watson has joined Aldershot, for duty, on arrival from Singapore.—Surgeon-Lieutenant Mitchell has been posted to Devonport.

Correspondence.

"Audi alteram partem."

THE OPIUM QUESTION.

To the Editors of THE LANCET.

SIRS,—I trust that it will not be considered an unkind reflection on the 5000 signatories of the anti-opium manifesto to suggest that there is probably a confusion in their argument where a clear distinction ought to be drawn. It arises from a certain ambiguity in the use of the word drug. On the abstract principle that any drug which has poisonous properties should be sold only under the regulations of the Pharmacy Act there is little dispute. On the practical point whether it is expedient that opium shall be sold in the countries to which it is indigenous only as a poison, experts of the highest authority give a negative answer. If we consider the subject medically we find that Sir Joseph Fayrer, Sir George Birdwood, Sir W. J. Moore, and many others well qualified to judge, affirm decidedly that the habitual moderate use of opium is not injurious, and that they "see no reason for abrogating the present regulations concerning opium in India." From the administrative standpoint we read that the Indian Government finds it to be the "unanimous opinion of its responsible officers that it is impossible to devise any machinery by which the consumption of opium could be suppressed, while the attempt to enter upon any such policy of suppression would involve gigantic evils" under the wholly different conditions of life and society in India compared with those in England. These evils are connected chiefly with the impossibility of preventing smuggling and illicit consumption, with the certainty of increasing the use of deleterious drugs, with disaffection caused by interference with national habits, and with revenue difficulties. If we look more to moral considerations we find that the large majority of Chinese opium-smokers are respectable people of the better class and well-behaved labourers, while carefully authenticated statistics of the frequenters of the Bombay smoking houses show that, "at the fewest, 70 per cent. are regular craftsmen and labourers." Mr. James, of the Bombay service, although opposed to the practice of smoking among Indians, testifies, "from his own observations when travel-

Digitized by Google

ling in the north of China, that opium smoking, in 99 cases out of 100 in China, is a harmless habit, like cigar smoking among Europeans."

To recur to the working of the abstract principle. Let us suppose that a European nation were under the rule of a Mahomedan power, and that, acting on principle, this Government decreed that alcohol, being a poison, should be sold only for therapeutic purposes. With what feelings would the ordinary "native" look upon the prohibition of taverns, beershops, and houses of public entertainment? Now consider the Mahomedans of India and the Chinese. They have not malt and hops, and they have not vineyards. Are we to prohibit their chief luxury for the sake of an abstract opinion, and because some enthusiasts picture imaginary evils? Rice, fruits, sweetmeats, and tea—are the races of the East to be limited to these alone? We cannot judge of the effect of habitual moderate use of an indigenous drug without seeing the conditions under which it is employed; but perhaps it will bring the question more home to English readers if we advocate the claims of a society for the total suppression of the trade in alcoholic beverages. This is more urgently wanted, more philanthropic, and equally practical with the scheme of the Society for the Suppression of the Opium Trade. We demand, in the first place, that our Government shall cease to derive any revenue from such a harmful drug as alcohol. We demand that our authorities shall not sanction by licence the infamous sale of a poison which has wrought incalculable harm. We can point to the multitudes in the East of the Mahommedan creed who do without spirits, and remark that even the millions of China produce very few drunkards. Why should not our Government stop the vice which reduces the morality of the public streets below the level of those of Eastern barbarians? If anyone wishes to know something of the issues involved in the opium question, let him procure the *Journal of the Society of Arts* for April 1st and the Blue-book on the Consumption of Opium in India, C. 6582, 1892. Dr. Watts' article on "East India Opium" is very full and instructive, and is published by Messrs. Eyre and Spottiswoode.

I am, Sirs, yours faithfully,

Watford, April 12th, 1892. W. D. SCOTT, M.D.

OPERATION FOR SPASMODIC TORTICOLLIS.

To the Editors of THE LANCET.

SIRS,—In an important annotation upon the subject of spasmodic torticollis in THE LANCET of March 26th you have directed the attention of your readers to the operative measures at present most relied on for its relief. Nerve stretching and nerve section having failed to have ever given more than temporary relief, the more drastic method of nerve excision and removal has been adopted; and as, like its predecessors, it is supremely empirical and unsupported by any pathological justification, it must also prove a failure. "Surgery," as Dr. Goodhart said, in his Harveian Lecture, "can happily accomplish now much of what it undertakes, but it needs to remember that it has not yet attained to the enucleation of the neurotic constitution. Operations of this kind are on a par with some of those on a painful kidney or the destruction of Meckel's ganglion for tic; they are conspicuous for the failure of those higher and more fundamental arts of treatment that should have lifted the patient over this necessity." The narrative of Keen's new operation for wry neck, and that of sympathisers nearer home, read so painfully like vivisection, from which even the inferior animals are saved by legal enactment, that such sections and dissections should not be sanctioned by the profession save as the *dernier ressort*, and after all the other resources of civilisation had been exhausted. As I have not observed in our medical periodicals any reference to a simple yet effectual plan of treatment adopted in an obstinate case of spasmodic torticollis by that eminent neurologist, Dr. Morton Prince, physician for nervous diseases to Boston City Hospital, U.S., and published in the *Boston Medical and Surgical Journal* of October 14th, 1886, I have to request the favour of its republication in your influential journal. Dr. Prince, taking for his text the title of an article which appeared in THE LANCET of July 12th and December 6th, 1884—viz., "Tenderness of the spine in health and disease, and the therapeutic effects of blistering over the region of [illegible] subject, and among other successful results of the treatment he mentions one of spasmodic torticollis as follows:—"The most strikingly successful case was that of a woman of about thirty to thirty-five years of age, who had been under treatment in the surgeon's room at the dispensary for about four or five weeks without any improvement; she was finally brought to me. At this time she complained of great pain and tenderness in the back of the neck, the pain shooting upwards over the back and sides of the head. The muscles of the back were stiff, almost rigid, the head being in one position. There was great tenderness over the cervical vertebræ, and the slightest jar on the top of the head or movement of the head caused intense pain; indeed, it had been thought there might be caries of the vertebræ, especially in view of the physical condition of the woman, which was that of anæmia and debility. Her expression was indicative of prolonged suffering; there was also enlargement of the submaxillary glands. Finding also tenderness over the fourth and fifth dorsal vertebræ, I directed that a blister be placed over that region. The next day the woman returned, presenting an entirely different picture. The pain and tenderness were gone, the motion of the head was natural, and the look of suffering had disappeared from the face. Of course the pleasure exhibited by the patient at being at last relieved from pain was what might have been expected. She afterwards had some trouble with the enlarged glands, but the above symptoms never returned. I saw her about a year afterwards, when she stated she had had no return of the symptoms. Two other cases of the same character, but of less severity, were equally successful. One was that of a man whose surprise and delight at his sudden cure were truly comical. I have tried the treatment in one case only of vomiting of pregnancy, when it was eminently successful." He concludes his paper with this sentence: "Decided and beneficial effects may often be obtained by blistering over the fourth and fifth dorsal vertebræ in various neuroses."

I am, Sirs, yours faithfully,

ALEXANDER HARKIN, M.D., F.R.C.S.

Belfast, April 2nd, 1892.

SMALL-POX TRAMPS: WHO IS RESPONSIBLE?

To the Editors of THE LANCET.

SIRS,—I beg to lay before you the following case:—A "tramp" walked into the waiting-room of an infirmary the other day and stayed there until the house surgeon came in, who instantly diagnosed the case as one of small-pox; this was confirmed by other members of the staff soon after. The fact was then announced to the committee, which was at the time sitting, who immediately communicated it to the medical officer of health. This occurred about one o'clock P.M. The medical officer of health, after consultation with some members of the Town Council, decided that the sanitary authorities should not be called upon to take charge of the case; and the sick man was allowed to stay at the infirmary until the evening, when the relieving officer was requested to take him to the workhouse. He replied he had instructions not to do so, the sick man being "no pauper until he sought relief," and he declined to do anything in the matter, both the sanitary and the parochial authorities thus throwing the responsibility on the infirmary. A consultation was consequently held by two of the medical staff, who came to the conclusion that it was not consonant with the safety of other patients to admit the case into the house, there being no convenient arrangement for the treatment of small-pox. The poor man was therefore told he could not be attended to, and that the doors were open to him to go out. He took the hint and walked away. The case being one of modified small-pox, he was able to go as he had come in. In the course of the night the police took him to the relieving officer, who then took charge of him and provided him with lodgings. Subsequently the sanitary authorities stepped in. This case has caused great altercation among the authorities. I have endeavoured to state it as accurately as I can. Will you or anyone kindly inform me as to who was wrong in not taking the responsibility and not providing for the requirements of the case in the first instance?—I am, Sirs, yours faithfully,

April, 1892. A CONSTANT READER.

* * The above letter is very curious reading, [illegible] our boasts of sanitary legislation and [illegible] England. We feel inured to [illegible] of small-pox [illegible]

who, in a bad plight on the road, was passed by many persons, who contrived to convince themselves that *they* were not his neighbours, and were under no neighbourly obligations to him. We shall undertake at once to close all controversy on the above subject by declaring our opinion that the sanitary authorities were the principal culprits. The pedantry of the relieving officer is bad enough—excusing himself and his masters on the ground that the actual small-pox patient had not come to his door *in formâ pauperis*, though application was made on his behalf. But the action of the sanitary authorities quite eclipses that of the relieving officer and those who gave him his instructions. We can scarcely believe our eyes in reading that the medical officer of health, after consultation with some members of the Town Council, decided that the sanitary authorities should not be called on to take charge of the case! This is very much like the responsible officers at a fire station telling an urgent messenger that *they* should not be called on to put out a fire. What are we coming to? For what do sanitary authorities exist, if not to deal with a tramp suffering from small-pox, with a thousand thanks to anybody who will announce his presence and his movements, and to take immediate and entire charge of him, and all exposed to his infection, till all risk of further spread of the disease was over? The only approach to the Good Samaritan in this case was in the authorities of the infirmary.—ED. L.

THE CÆSAREAN OPERATION: A SUGGESTION.

To the Editors of THE LANCET.

SIRS,—The risk of fatal peritonitis supervening upon Cæsarean section, especially when the fœtus is putrid, might, it appears to me, be greatly reduced if the operation were performed in two stages, instead of one as at present. Other abdominal viscera and some intra-peritoneal abscesses are commonly treated in two operations when a communication with their interior for some purpose has to be established, and I would suggest a similar method of dealing with the uterus in Cæsarean section. At eight months and a half an incision through the abdominal wall sufficiently large to admit of the withdrawal of the fœtus might be made, and the edges of the wound accurately and carefully stitched to the uterus, as to the stomach in gastrostomy. Then at full term, when adhesions around the wound had shut out the peritoneal cavity, the second operation of opening the uterus and delivering might be performed with the minimum of risk as being extra-peritoneal. I do not think the after-treatment would be rendered more difficult. Post-partum hæmorrhage could be as easily controlled as at present. The adherence of the uterus to the abdominal wall might interfere with uterine contraction and complete sub-involution—to what extent experiment alone would decide; but as adhesions between the uterus and the abdominal wall generally form after Cæsarean section, the uterus would doubtless adapt itself in some way to its new anchorage. The uterine and abdominal incisions could be closed simultaneously at the second operation, drainage being arranged for by the cervix or abdominal incision, at the discretion of the operator. Further details of the operation would have to be considered.

I am, Sirs, yours obediently,

Margaret-street, W., April 20th, 1892. J. H. DAUBER.

A CORONER ON UNQUALIFIED ASSISTANTS.

To the Editors of THE LANCET.

SIRS,—It is observed in an article in THE LANCET of the 16th inst., on the death of Miss Bradshaw at Luton, that my connexion with Mr. Beart and non-appearance in the case require explanation: First, on Saturday I was called away on private family business before Mr. Beart could communicate with me, there being, as I thought, nothing serious to attend to. Had it been possible to send to me in time for the inquest I should have been there; but the coroner did not ask for me. Secondly, Mr. Beart has worked with me for ten years, and has always called me to any serious case under his care *at once*. This he was for once unable to do, but in his evidence states that he told them to send for someone else if the patient became worse. Mr. Beart has never, to my knowledge, represented himself to be other than an unqualified man. I scarcely think even an unqualified man, after twenty-five years' successful work under very competent surgeons, could make any gross blunder. In Dunstable he has earned a local reputation in obstetric cases. His prescriptions were produced in court, and I see no evidence of malpraxis or negligence. I see that the Home Secretary, acting on the actual depositions, and not a mere newspaper report, has declined to interfere.

I am, Sirs, yours truly,

Dunstable, Beds., April 19th, 1892. F. W. D. HENSLOWE.

THE ROYAL BRITISH NURSES' ASSOCIATION.

To the Editors of THE LANCET.

SIRS,—The application which the Royal British Nurses' Association has recently made to the Lords of the Privy Council for a charter of incorporation has led to the publication of certain articles and letters which are calculated to convey the following inferences: that there exists a body which is empowered to represent the collective opinions of the nurse-training institutions; that such a body is opposed to the petition and aims of the Association; that the register of trained nurses which is maintained by the Association is calculated to mislead the public and to be detrimental to the interests of the best class of nurses. In view of the fact that the questions thus raised will shortly be argued by counsel and judicially decided, the Association has thought it becoming to abstain from offering any specific or detailed reply; but, at the same time, it desires to make known that it is in a position to meet all such statements and implications with positive denial and effectual refutation.

We are, Sirs, your obedient servants,

CATHERINE J. WOOD,
W. BEZLY THORNE, M.D., } Hon. Secs.

THE SHOP HOURS QUESTION.

NATIONAL CONFERENCE AT MANCHESTER.

(FROM OUR SPECIAL CORRESPONDENT.)

THE Conference convoked to consider the Parliamentary aspect of the shop hours question has most emphatically confirmed and accentuated the evidence and arguments brought forward in the Reports of THE LANCET Special Commission on "Sanitation in the Shop."[1] The Conference was organised by the National Union of Shop Assistants, and met at Manchester on Easter Monday. It was thrown open to any association connected with retail trades, irrespectively of trade or sex, and whether representing the employed or the employers. Consequently the Women's Trade Union League was represented by Miss Marland, and the Master Grocers' Association of the Manchester and Salford district by four delegates. The shop assistants of Manchester, Salford, Sunderland, Newcastle, Middlesbrough, Jarrow, Liverpool, East London, Oldham, Ashton-under-Lyne, Barnsley, Leeds, Radcliffe, Cardiff, Swansea, Huddersfield, Bradford, Dewsbury, Hull, Leigh, Bolton, Wigan, Rochdale, Stockport, and Loughborough appointed delegates. Previously to the Conference the delegates of the various branches of the National Union of Shop Assistants held business meetings, where financial matters and the rules of their association were discussed and amended. Among other matters debated at this business meeting was the question of medical attendance. Complaints were made that some employers deducted 2*d.* per month from the salaries, and with this engaged a medical man to watch over the health of the assistants, and it was alleged that this arrangement was calculated to afford the shopkeeper timely warning, so that assistants could be discharged whose health was likely to fail. For about 2*s.* 6*d.* per annum per head the assistants could secure medical attendants who would not act in the interests of the employers, and this course was recommended to the various district branches; but each branch was left to do as it thought best, according to its

[1] See THE LANCET of February 27th and March 12th, 1892.

Digitized by Google

financial resources. The delegates also briefly discussed Mr. Provand's Bill, and passed the following resolution: "The National Union of Shop Assistants are unanimously of opinion that nothing will effectually reduce to a reasonable limit the hours of labour in shops but an Act of Parliament, and the Bill introduced in the House of Commons by Sir John Lubbock is the most practical of any of the schemes before the country at the present time." This resolution was accepted unanimously, and signed by all the delegates.

In the afternoon the open conference was held in a room lent for the purpose by the Young Men's Christian Association. Mr. H. J. Roby, M.P., was in the chair, and Mr. W. Mather, M.P., who is a member of the Select Committee on Mr. Provand's Bill, was also present.

Mr. Roby, M.P., in opening the proceedings, took a cheerful view of the situation, inasmuch as in the present instance the interests of the employed and of the employers were identical. Both would benefit by shorter hours. As for the public, so long as shops were open they would choose their own time; but it was not impossible for the public to shop earlier in the day. Throughout the country the movement in favour of limiting the hours of labour was spreading fast; and this was shown by the introduction of the Miners' Eight Hours Bill. On inquiring whether such limitation should be obtained by consent or by legislation, the speaker was met by loud cries in favour of legislation. He acknowledged that the tendency of the day was in favour of legislation; and such legislation was more easy with regard to the shop assistants, as it was not opposed by the employers. Mr. Roby insisted that all concerned should organise strong manifestations of opinion, and explained that Mr. Provand's view was that, while he doubted whether there was any chance of getting Parliament at present to limit the hours of grown men, a beginning might be made, as in the case of the Factory Acts, with the women, and thus Parliament would get accustomed to this principle of State intervention. At first there would be great opposition from both sides of the House to limiting the hours of adult males; but still, if they could show that such limitation was reasonable, and that the great majority of the trades concerned approved of such legislation, for his own part he thought they would ultimately succeed.

Mr. R. Davis of Cardiff, president of the National Union of Shop Assistants, then addressed the meeting on behalf of the Union. He urged that if any section of the community suffered, and were degraded physically and morally, this would not fail to affect the nation as a whole. There was danger in neglecting such matters. Mr. Provand had proposed to fix the maximum number of working hours per week. Sir John Lubbock would reduce the hours of work by allowing the majority of shopkeepers to fix the time of closing at night. At present they were constantly beaten by a small minority of shopkeepers who would not close early. At Swansea a canvass, undertaken conjointly by the Trades Council and the master shopkeepers, had shown that 98 per cent. of the shopkeepers, even in the poorest quarters, were in favour of early closing. For the last twenty years they had enjoyed the half-holiday in South Wales; yet, though so long established, this was only maintained by constant advertising and agitation. They wanted the law to render them secure in the possession of what they had so much trouble to maintain. As for the demonstrations of opinion which Mr. Roby desired, it was impossible for shop assistants to get employment without a reference, and many employers gave bad references to assistants who took public action. The master grocers of Liverpool had draughted a Bill in favour of closing at 7 P.M., and at the Master Grocers' Congress, recently held at Birmingham, the proportion of grocers in favour of early closing was in the ratio of 10 to 2. The degradation and the misery of shop assistants were such that parents were now beginning to make skilled artisans of their children instead of sending them to shops. Instead of working twelve hours a day as a shop assistant for 3*s.*, it was better to work eight hours a day for 6*s.* as a skilled artisan. The result was that experienced and really good shop assistants were becoming more and more scarce. A lower class of persons worked in shops, and these were more easily victimised. He also urged that public health and public morality had much to gain by early closing. [illegible] to get [illegible] to shop the husbands [illegible] to be [illegible] to the public [illegible] [illegible] [illegible]

instead, and many thousands of unfortunate girls would be thrown on to the street.

Mr. Davis, on behalf of 1200 organised shop assistants of Wales, of which one-sixth were women, said he did not approve of Mr. Provand's Bill.

Mr. Mathers, M.P.: "Then you all agree in condemning Mr. Provand's Bill?" At which there were some cries of dissent, one delegate rising to protest that, though the Bill was incomplete, insufficient, and unjust in its special treatment of women, still he would prefer such a Bill to no legislation at all. Several delegates seemed to agree with this opinion. The Conference then unanimously adopted the resolution introduced by Mr. Williams, as mentioned above, which suggests the amendments necessary to render Mr. Provand's Bill satisfactory, together with another resolution, to the effect "that all *employés* in these industries shall come within the jurisdiction of this Act, without distinction of age or sex."

Mr. Rowe of Manchester then read a paper on the Living-in System. For motive of economy, convenience, and discipline shop assistants were made to board on the premises. By this means they were disfranchised as Parliamentary voters, and were kept under an iron rule. They were harassed by any number of petty regulations, had no sense or enjoyment of home; the sanitation was vile, the table a snare and a delusion. The food was coarse; they were constantly disturbed at their meals to serve customers. It was a survival of the truck system in its worst form. What employers called plain fare meant workhouse rations, and the assistants were always obliged to be in by 10.30 P.M. No body of workmen would consent to be thus handed over body and soul to their employers, particularly as the acuteness of competition was rendering the employers more and more inhuman. The rate of wages was calculated on the basis of bare subsistence for a single man. Consequently, if a shop assistant wished to marry, he was discharged from his employ. The speaker protested that celibacy was contrary to the scheme of nature, and claimed for the shop assistants their natural right to marry. Sir Bartle Frere had raised the indignation of the British public by relating that the Zulu warriors lived in enforced celibacy. The British public were now invited to consider the condition of the assistants who worked in shops, which, in consequence of the enforced celibacy, had become hotbeds of immorality. He would not insist, he would draw the veil over this question; but if our social conditions were such as to render vice so attractive and virtue so repulsive, nature would surely take her revenge. Shop assistants were no worse than any other class, but, like others, had to yield to the force of surrounding influences. If these influences were exceptionally bad, the result would be evil in due ratio. Why also did it happen that there were so few elderly men among the shop assistants? The fact was that old men were flung out to swell the army of the unemployed. Members of Parliament knew little or nothing of their position; this was proved by the recent debates. Shop assistants had no votes, nor did their case present features out of which party cries could be contrived. But with the abolition of the living-in system they would acquire votes, and then redemption would draw nigh. Legislation must come; it was inevitable; the only question of doubt was how many more generations of shop assistants it would be necessary to kill off before such legislation became effective.

Mr. Davis was anxious the Conference should recognise that, if their interests had been neglected in some quarters, the press, in any case, had done a great deal to help the shop assistants.

Mr. Lomax of Loughborough had worked in a shop where during four years he never had an opportunity of putting on either his coat or his hat, except on Sundays. He left this place because he could not eat rotten potatoes. He had offered to eat half these potatoes if the employer would eat the other half, but this challenge was not accepted. At another shop he had good food, but not enough, so that his health broke down, and he went to work in the provinces. There, in one house, he found the food "was only fit for manure." One of the female assistants died, and, after her death, a bill was brought in for the food she had been obliged to purchase outside.

Mr. Almgilt of Barnsley related that at one of the most important shops in Sunderland, out of fifty assistants, only twenty were able to eat the food provided; they had to send out for food at their own expense. And the sleeping accommodation reminded him of what the third-class railway carriages used to be fifty years ago. At Hull he had found matters worse. There, after working for six months, he was so ill that he had to lie up for four months; net result, two months' profits. At Leeds he was also badly treated, but at Barnsley he had found a place where he had been able to build up his health again. But even here he had just lost a good companion, a fellow shop assistant, aged twenty-six, who had been dismissed for no other reason than that he was about to marry.

Mr. Macpherson (East London) thought that if male and female assistants were allowed to marry, they would become more settled and take a greater interest in the business. As it was, in many shops male and female assistants were dismissed if they were known to be in each other's company.

In answer to a question from Mr. Roby, M.P., Mr. Davis explained that in the provinces shopkeepers calculated the value of board and lodgings at 10*s.* a week; but he felt convinced that the board generally provided did not cost more than from 4*s.* 6*d.* to 7*s.* 6*d.* per head per week.

Mr. Jones described a firm which employed 200 assistants and only allowed their housekeeper 9*d.* per head per day for the food supplied. Was it possible that full-grown men, working hard all day, could be kept in a wholesome manner on 9*d.* per day?

The Congress then carried unanimously a resolution to the effect that "the living-in system should be abolished." This concluded the business, and after the usual votes of thanks the Conference adjourned.

It will be seen by the opinions expressed and by the evidence incidentally given in the course of the speeches briefly summarised that the views expressed and the facts described in the Reports of our Special Commission are fully borne out. The long hours, the want of freedom, the bad food, the bad sanitation—these are the main grievances. Legislative interference on behalf of the men as well as the women is considered the only means by which the moral, the material, the sanitary, and the social condition of the shop assistants can be improved.

Manchester, April 19th.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Medical Appointments.

AT a meeting of the board of guardians, held on the 20th inst., Drs. T. S. Short, J. O. W. Barratt, and A. H. Carter were elected visiting physicians to the infirmary. Some interest has attached itself to these appointments, since it was with a view to permitting their officers to apply that the rules of the General Hospital were lately altered. A wider range of choice is thus given to the guardians, along with the opportunity of securing the services of the best candidates. The first of the above-named gentlemen is at present assistant physician to the General Hospital, the second holds no hospital appointment, and the third is senior physician to the Queen's Hospital. The contest for the appointment of physician to the General Hospital, owing to the resignation of Dr. Wade, promises to be a close one, and is giving rise to some excitement. The election will take place on May 4th, and the elective body consists of the committee, *plus* fifty subscribers chosen by ballot. Dr. Foxwell, physician to the Queen's Hospital, and Dr. Wilson and Dr. Short, assistant physicians to the General Hospital, are at present the only candidates. Various interests are brought to bear in support of the claims of each, and the voting promises to be close.

The Workhouse Water-supply.
